## ACKNOWLEDGMENTS.

The following-named gentlemen have assisted in the preparation of this volume:

Mr. George H. Willson, local forecaster, and the following members of the office force at San Francisco. Mr. Horace E. Smith, Mr. William Norrington, Mr. Walter H. Scholl, Mr. William J. Reed, Mr. Herbert E. Wilkinson, Mr. Hugo Legler, Mr. Walter J. Bennett, and Mr. William H. Fahlbusch.

Mr. George E. Franklin, local forecaster, Los Angeles, Cal., contributed the article upon the "Climate of Los Angeles;" Mr. James A. Barwick that upon the "Climate of Sacramento;" Mr. Ford A. Carpenter, the "Climate of San Diego;" Mr. Maurice Connell, the "Climate of Red Bluff;" Mr. Aaron H. Bell, the "Climate of Eureka;" Mr. J. P. Bolton, the "Climate of Fresno;" Mr. J. R. Williams, the data for San Luis Obispo, and Mr. J. J. McLean the data for Independence.

The Southern Pacific Company has for many years had its agents keep a daily record of rainfall and temperature, which records have been compiled by the Weather Bureau office at San Francisco. Data from 181 stations in California have been thus collected. Through the courtesy of the Santa Fe System reports from ten stations in the San Joaquin Valley are received.

Due credit must also be given to the voluntary observers of the State; and in particular to Mr. Samuel H. Gerrish, Sacramento; Mr. J. A. Edman, Edmanton; Mr. J. C. Stanton, Rio Vista; Mr. C. W. Hendel, La Porte; and Dr. C. Max Richter, of Santa Barbara. The records, journals, and diaries of Thomas Tennent, Dr. G. H. Gibbons, Dr. T. A. Logan, and Mr. John Pettee have been generously drawn upon for data. To these records we are indebted for all data preceding the period of regular Weather Bureau observations.

Mr. J. B. Lippincott, of Los Angeles, resident hydrographer of the United States Geological Survey, has kindly placed at our disposal the rainfall data at high altitudes used by him in his engineering practice. In California seasonal rainfalls and data showing probable water supply in various drainage basins are of the utmost importance to the engineering profession. In the present paper many fragmentary rainfall records had to be omitted in order to keep the volume within reasonable limits. Many of these can be found in "Irrigation and Water Storage" by Glassford.

The diagrams of rainfall in this memoir show the seasonal amounts, because for engineering and other purposes the seasonal rather than the calendar year totals are desired. In the various tables, however, it was thought best to continue the usual yearly amounts.

The table of elevations has been materially changed and many corrections made by Prof. George Davidson and Prof. Joseph N. Le Conte, both of the University of California.

# CLIMATOLOGY OF CALIFORNIA.

## CONTROLLING FACTORS.

The general climatic conditions of the Pacific coast, and particularly the climate of California, may be said to be controlled by four great factors. These are

1. The movements of the great continental and oceanic pressure areas—the so-called permanent “highs” and “lows.” Under this head we include also the most active factor in climatic development, namely, the movements of individual pressure areas, since there is now good ground for believing that the paths of these individual disturbances—large-sized whirls and counter whirls—are largely determined by the general relations of the permanent pressure areas;
2. The prevailing drift of the atmosphere in temperate latitudes from west to east;
3. The proximity of the Pacific Ocean with a mean annual temperature near the coast line of about 18° C. (65° F.), a great natural conservator of heat, and to which is chiefly due the moderate range of temperature along the coast from San Diego even to Tatoosh Island; and
4. The exceedingly diversified topography of the country for a distance of 200 miles from the coast inland.

## PRESSURE DISTRIBUTION.

It was early shown by Hoffmeyer that the distribution of the great so-called permanent-pressure areas over the North Atlantic Ocean determined largely the character of the seasons in northern Europe. Teisserenc de Bort, discussing the causes of an abnormal winter in central Europe, called attention to the fact that during this period the great high-pressure area ordinarily overlying the Atlantic Ocean between latitudes 20° and 40° north had moved somewhat from its normal position. Elliot, Blanford, and others have shown that the great atmospheric movements over India are more or less connected with the chief features of the weather there, particularly with respect to the monsoons and rainfalls. Fassig has recently shown that the weather conditions prevailing in the United States east of the Rocky Mountains during March may be connected with the movement of the large pressure areas; and, in brief, that the weather of the Middle Atlantic States “is cold when the continental high controls, warm when the Atlantic high extends its influence westward beyond the coast, and normal when there is a fairly equal development in strength and extent of the two high areas, in which case now one, then the other, is in control of the wind direction, bringing alternately cold and warm air to the region. The paths of storms lie within the trough between the two high areas; when the trough is wide the storm paths are widely scattered; as the high areas approach one another the storm paths are contracted within narrower limits.”

Over the North Pacific Ocean in winter there exists an area of low barometer covering the region between the latitudes of 40° and 60° north and 130° west to 140° east longitude. An area of high pressure overlies the greater part of North America with a southwest extension to the Tropics and west to the one hundred and sixtieth meridian. We shall find that typical wet winters on the California coast occur when this great North Pacific low extends well eastward overlying the continent west of a line drawn from San Francisco to Calgary. At the same time the great continental high area apparently recedes to the southeast. On the other hand, the

pressure distribution characteristic of a dry winter on the California coast is marked by the prevalence of the continental high over the entire country west of the Rocky Mountains. This relation is very clearly shown in the series of four charts following taken from Prof. A. J. Henry's "Rainfall of the United States." Professor Henry states "The prevailing winds and the pressure distribution shown on the chart for December, 1880, are favorable for heavy precipitation in California and the plateau region. The pressure distribution is abnormal, as is also the rainfall; \* \* \* the chart represents an extreme condition, viz, a transfer of the usual track of low pressure areas of the northern boundary southward to central California and the plateau region of Nevada and Arizona, \* \* \* this region being ordinarily covered by an area of high pressure."

This relation of permanent pressure distribution and rainfall is more plainly shown on the series of charts for December, 1901, January and February, 1902. December and January were months of marked deficiency in rainfall, and it will be noted that during this period the continental "high" overspread nearly the entire country west of the Rocky Mountains. The prevailing air movement in California under such conditions is from the north or northwest and, as might naturally be inferred, such a circulation is accompanied by scanty precipitation. During February, however, there is a noticeable change in pressure distribution. The continental "high" is now well to the east of the Rocky Mountains, while the North Pacific "low" has apparently moved well in over Vancouver Island and Washington. The general air movement is now from the south and southwest and the rainfall very heavy, especially in the northern coast counties of California. At some places in the redwood section the rainfall amounted to as much as 40 inches during the month.

No one who has not lived in California can realize the relief which this generous rainfall of February brought to an anxious community.

The extensive record of rainfall at San Francisco, covering a period of fifty-three years, may be studied to advantage in connection with the pressure distribution. There were six Decembers during which the rainfall exceeded 10 inches, the normal December rainfall being 5 inches. These months were in 1852, 1866, 1867, 1871, 1880, and 1889. The pressure distributions for the earlier years are not available, but the conditions for the month of December, 1880, are characteristic and are shown in detail in the charts here given. The mean rainfall for December at this station is about 5 inches; the greatest rainfall was in 1866, when 15 inches fell. In 1871 14 inches fell. The driest December on record was that of 1876, when no rain fell during the entire month. Pressure charts are not available, but the probability is that the chart would greatly resemble that given for December, 1901. There were seven Decembers in this period in which the total monthly precipitation did not exceed 1 inch.

For January a similar relationship is found to exist. In 1862 the rainfall exceeded 24 inches, or nearly five times the normal amount. In 1866 over 10 inches fell; in 1878 nearly 12 inches, and in 1890 over 9 inches. The driest January of recent years was in 1891, when less than 1 inch fell. The pressure distribution is that of the type shown by 1892 and 1889. For February the mean rainfall is about 3½ inches. In 1878 over 12½ inches fell; in 1887 over 9 inches. In 1891 the February rainfall was 7.26 inches and in 1902, 7.27 inches. It is interesting to note that the pressure charts for these years closely resemble each other over the country west of the Rocky Mountains. On the Atlantic seaboard the pressure distributions are not alike.

Pressure, Wind, and Rainfall during a Dry winter month.—January, 1889.

Pressure, Wind, and Rainfall during a Wet winter month.—December, 1889.

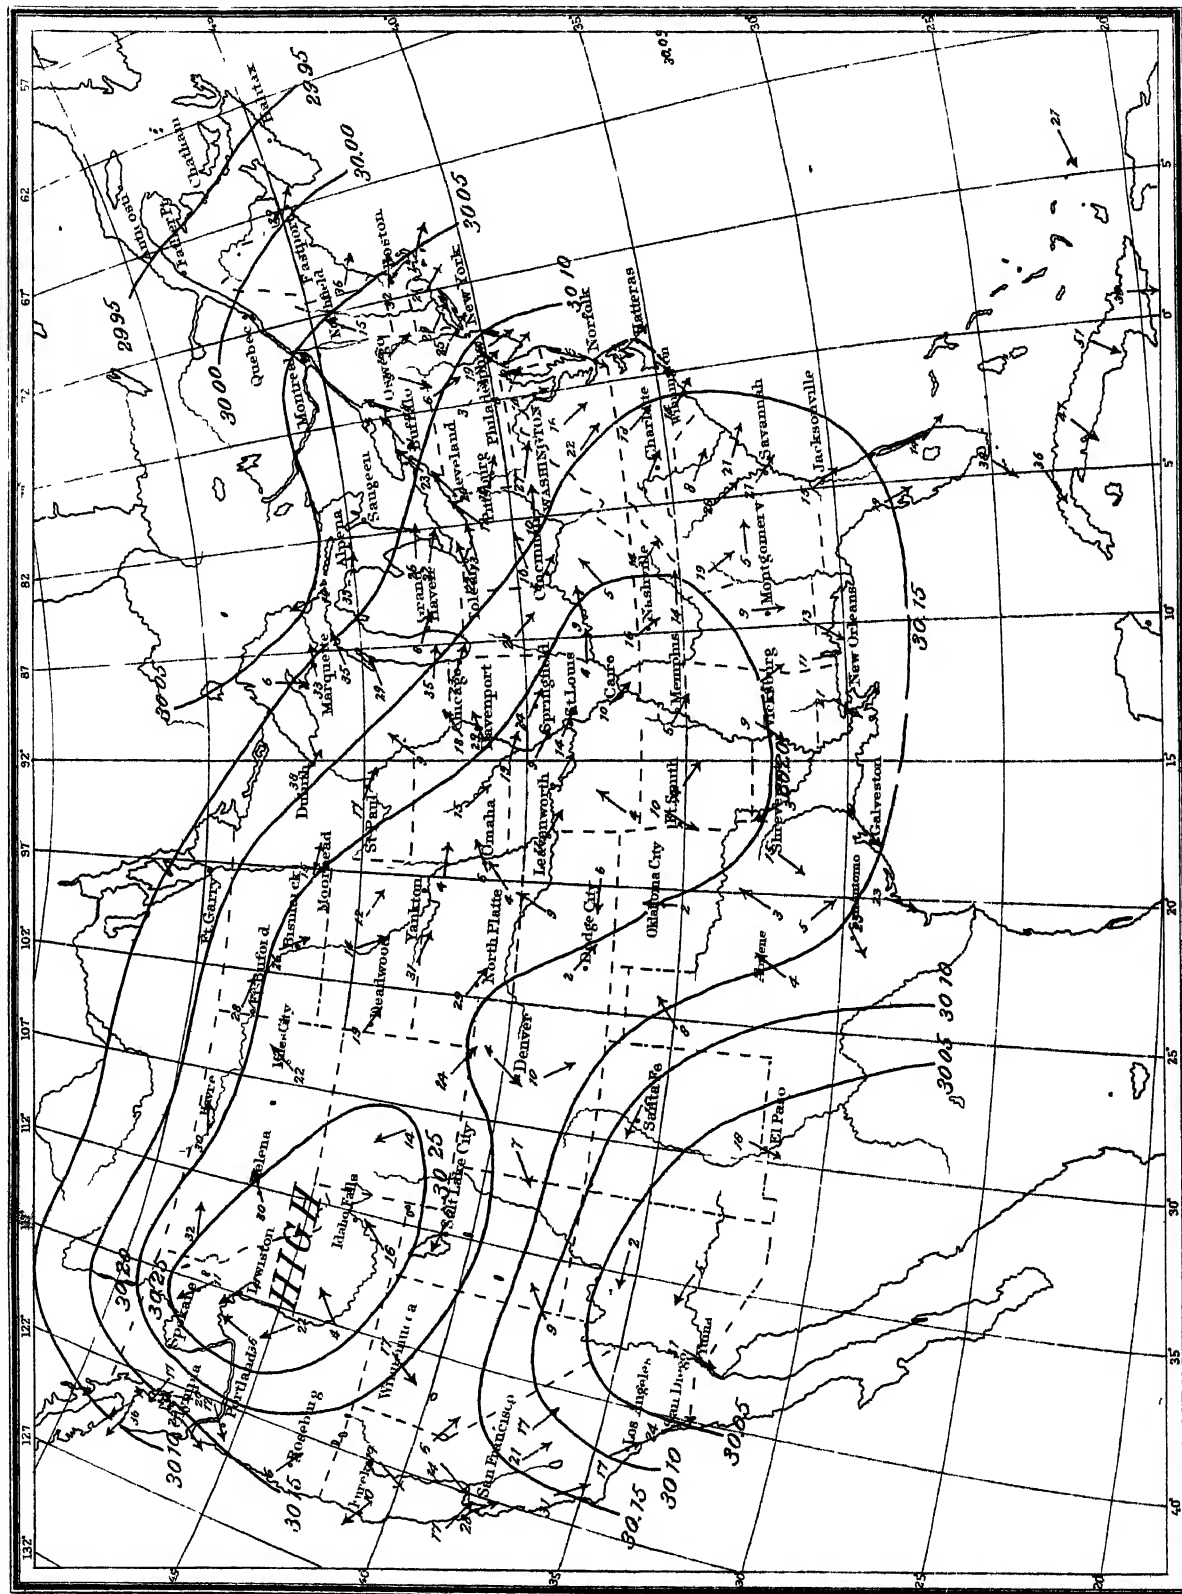

Sea-Level Pressure; Resultant Surface Winds, January, 1902.

Sea-Level Pressure; Resultant Surface Winds. February, 1902.

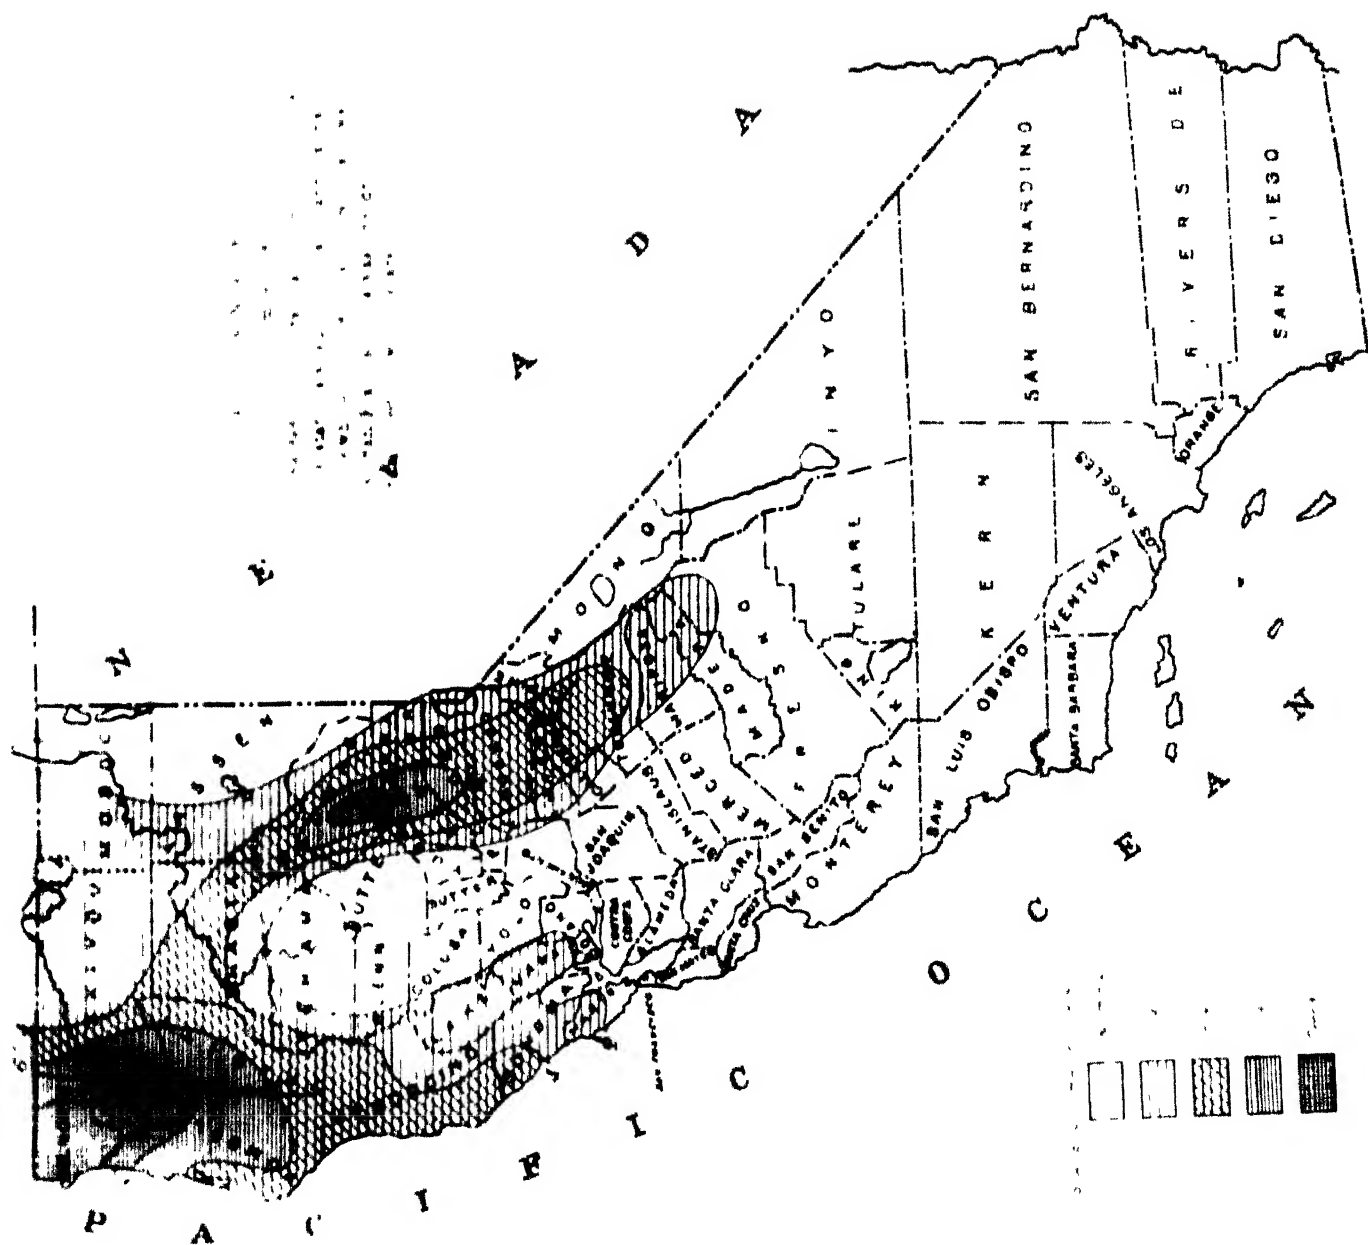

PLATE 5.

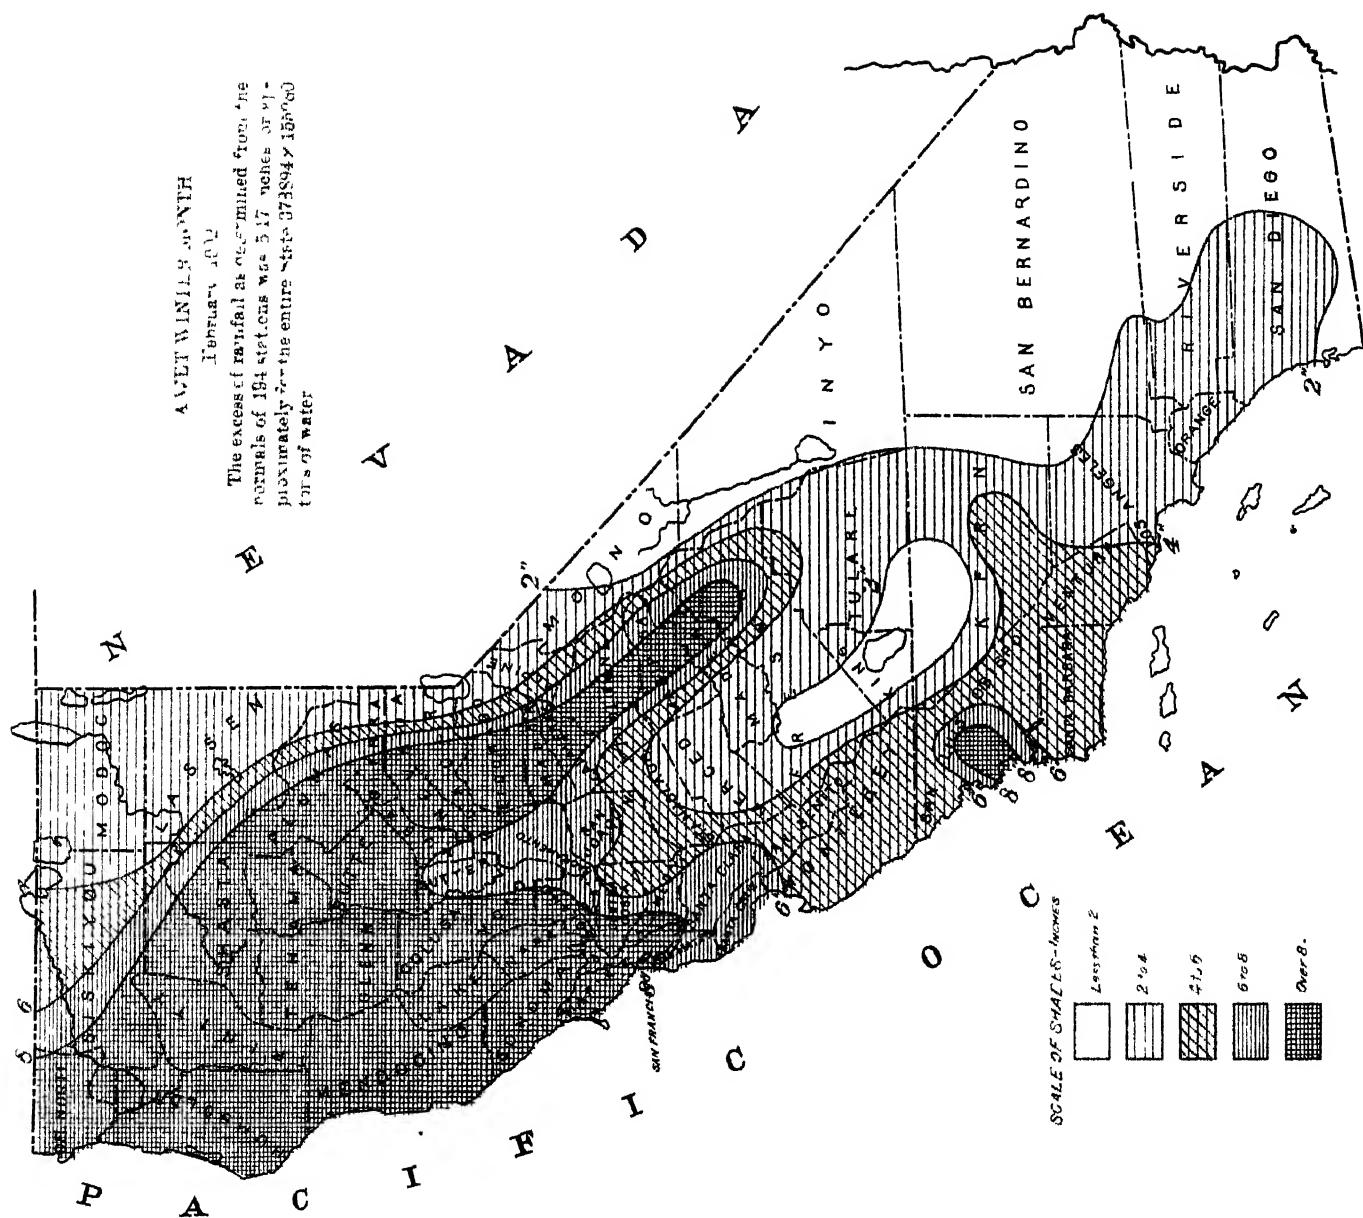

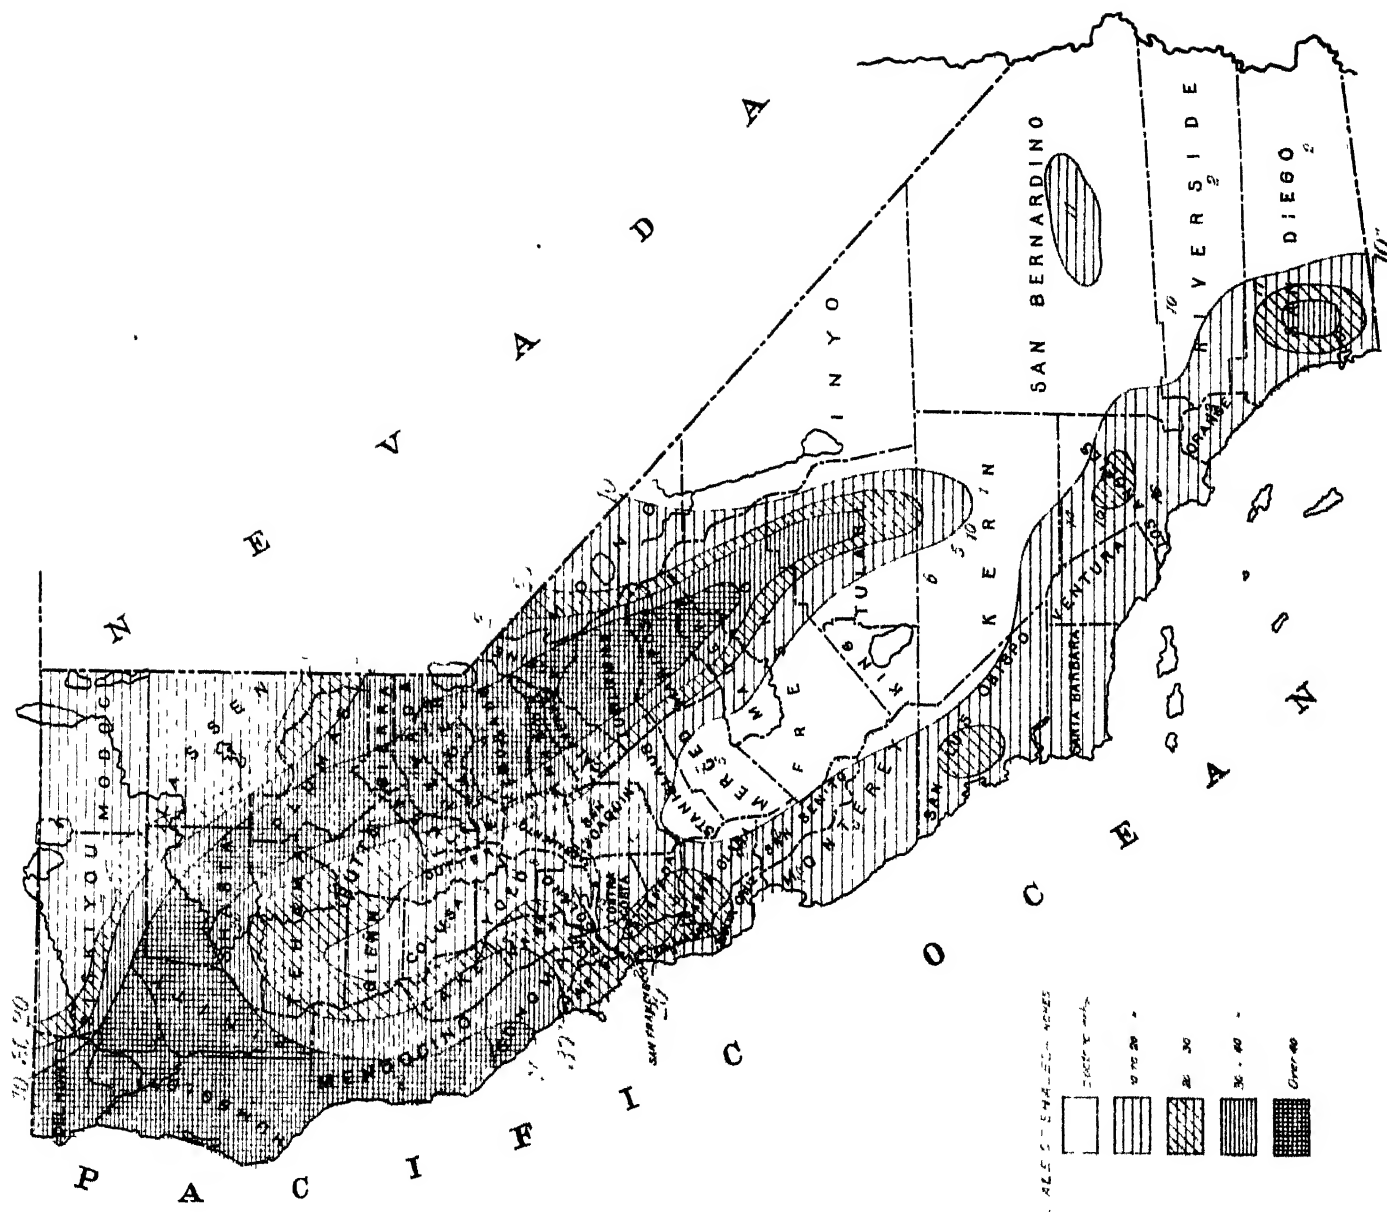

Based on 20 years record and 1 year of normal rainfall, as determined for the above record.

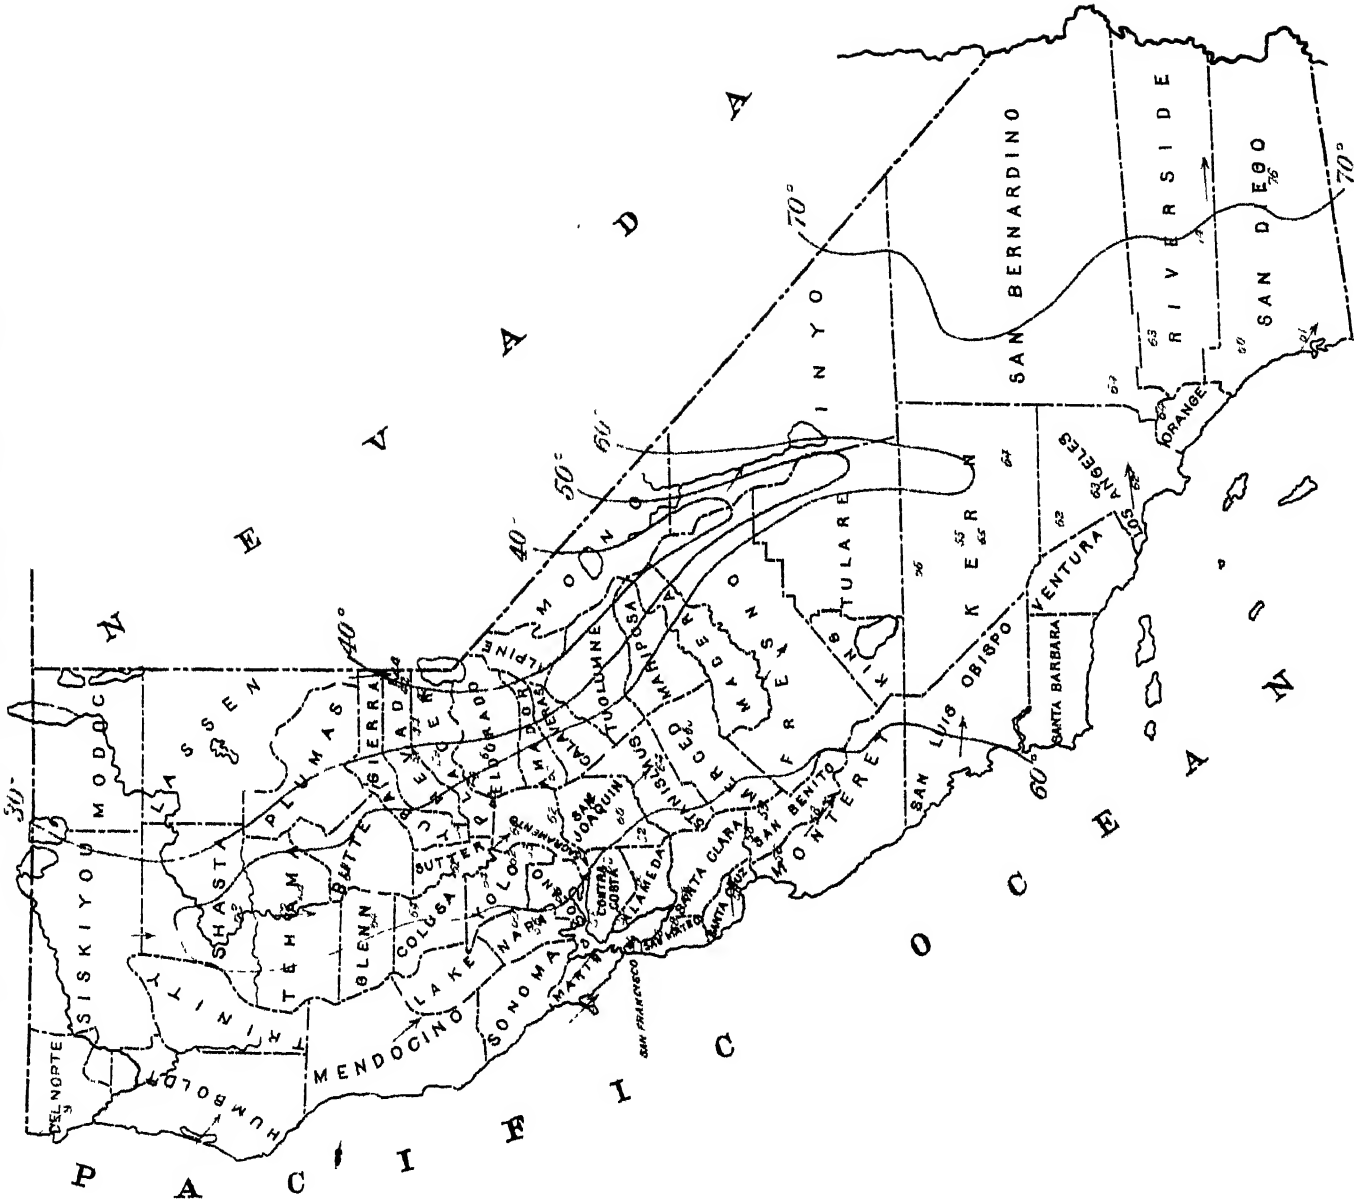

Based on 20 years experience and 1 year of normal "airmail" as determined by the 2nd airmail section.

Mean Annual Isotherms and Prevailing Winds Based on 20 years' normals.

FIG. 1.—Seasonal rainfall at San Francisco, 1900-1911.

FIG. 2.—Seasonal rainfall at San Francisco, Cal. Intensity or amount in inches. (Normal, 23 inches)

FIG. 3.—Seasonal rainfall at San Francisco, Cal. Frequency, or number of days. (Average, 71 days.)

A study of the charts in the Monthly Weather Review makes plain the positive character of the relationship between pressure distribution and the amount of rainfall. It will probably be found upon investigation that the frequency of rainfall as well as the intensity bear a direct relation to the pressure distribution as described above. In addition to the charts of the Monthly Weather Review excellent material for a further study of these relationships is to be found in the various international bulletins and synoptic charts of the various meteorological services.

The path of storms will be determined by the position of the great permanent areas. When the North Pacific low extends well to the southward in winter the storm tracks are well to the southward. And conversely if far to the north, the mean paths will also be far north.

#### MOVEMENT OF AREAS OF HIGH PRESSURE.

By referring to the charts published in the Monthly Weather Review it will be seen that, especially during winter months, areas of high pressure frequently lag in their eastern march over the country between the Sierra and Rocky Mountains. Such conditions are alluded to elsewhere as being generally accompanied by tule fog in the great valleys with temperatures ranging from  $30^{\circ}$  to  $40^{\circ}$  at sea level and from  $40^{\circ}$  to  $50^{\circ}$  at an elevation of about 1,000 feet. Warm weather with high northerly winds is apt to prevail in southern California during the early part of the winter, while, strangely enough, under somewhat similar conditions of pressure distribution during January and February, cool nights with frost in the morning may be expected in southern California.

During the prevalence of a slow moving area of high pressure it has been found that depressions of moderate depth sometimes develop on what may be called the periphery of the high to the south and southwest. During the months of November, December, and January under such conditions rain will begin falling without much warning along the coast from Point Conception southward. The forecast official can from the very nature of things give but little advance warning of such disturbances.

#### MOVEMENT OF AREAS OF LOW PRESSURE.

##### STORMS OF THE WEST PACIFIC OCEAN.

A discussion of these storms falls more properly under the province of the Hydrographic Office; but so interesting are the few facts which are fairly well established that brief mention must be made of them. The typhoons of the West Pacific have been studied with much care and skill by the staff of the observatory at Manila, and particular mention must be made of the work of the director of the observatory, P. José Algué, S. J., and P. Juan Doyle, S. J., subdirector of the observatory. Algué's "*Baguios ó Ciclones Filipinos*" and Doyle's "*Tifones del Archipiélago Filipino y Mares Circunvecinos*" are the best contributions to the subject.

Excellent directions for mariners and much information of a practical character is to be found in *The Law of Storms in the Eastern Seas*, by W. Doberck, director of the observatory at Hongkong. The observatories at Tokyo and Shanghai have also collected much material relating to storm development and motion on the Asiatic coast. Reference should also be made to the work of Dr. Paul Bergholz, director of the meteorological observatory at Bremen, who has given special attention to the storms of the East Indies. A translation of an address by this author on "*The origin, paths, and limiting zones of the typhoons of the Orient*," by Professor Abbe, was published in the Monthly Weather Review for September, 1899, and an abstract of this follows:

## TYPHOONS OF THE PACIFIC OCEAN

The following table shows at a glance a classification of the hurricanes of the Pacific Ocean.

*Typhoons of the Pacific Ocean*

Group	Months	Trend of first branch, <sup>a</sup>	Latitude of vertex of parabola	Trend of second branch
1. .	December . . . .	North-northwest . .	15-19	North-northeast
	January . . . . .			
	February . . . . .			
	March . . . . .			
2. . . . .	April-May . . . . .	Northwest . . . . .	16-21	Northeast.
	May . . . . .			
	October . . . . .			
	November . . . . .			
3. . . . .	June . . . . .	Northwest by north,	21-25	Northeast by east
	July . . . . .			
	August . . . . .			
	September . . . . .			

<sup>a</sup>Namely, when passing the small circle of latitude for Manila

In general, the paths of these hurricanes are all parabolic. The average trend of the paths or the inclination to the meridian is much larger when they pass the latitude of Manila ( $14^{\circ} 35'$  north) than the average trend in the first branch. This is particularly noticeable during the months of the first group, and this evidently results from the fact that the latitude of the intersection [vertex?] of the path agrees very nearly with the latitude of Manila.

If now, with the assistance of the charts of isobars, we determine the conditions under which the cyclones are formed in the different months and groups of months, we find.

(a) The paths of the hurricanes of the Pacific Ocean in the first group start from the region between two areas of high pressure, one of which lies over the continent, the other over the Pacific Ocean. They lead toward the center of low pressure that occupies a portion of Bering Sea. The hurricanes of the China Sea keep within lower latitudes, namely, those which are reached by the limiting isobars of the Asiatic center of high pressure. In proportion as the centers of high pressure flatten out and withdraw during the period from January to March, so these extreme isobars retreat toward the north, and consequently the paths of the hurricanes extend farther north.

(b) With reference to the second group, the charts of monthly isobars show that the hurricanes of the Pacific Ocean in April and May move between the extreme isobars of the high-pressure areas of the Pacific Ocean and Asia.

(c) The paths of the hurricanes of the China Sea keep south of the isobar 760 mm, belonging to the high-pressure area of Asia and the low-pressure area of Hindostan. In October and November, in proportion as the Asiatic high-pressure area develops, these are pushed more and more into lower latitudes, moreover, the development of the area of low pressure in Hindostan is an index to these paths.

(d) The hurricanes of the Pacific Ocean, especially in October, pass along the broad zone between the Philippines and Japan, on the one hand, and the isobar of 760 mm surrounding the high-pressure area of the Pacific. In November this zone becomes narrower by reason of the further development of the continental area of high pressure. The hurricanes of the Pacific Ocean belonging to this group also pursue paths toward the depression in the extreme north, which bears north-northeast from Manila.

(e) It is characteristic for the months of the third group that from June to September, at least to the middle of the latter month, the center of high pressure withdraws from the coast of Asia, and finally disappears. In connection with this the paths of the hurricanes attain higher latitudes, and those of the Pacific Ocean recurve very near the meridian of  $125^{\circ}$  east, therefore nearer to the Philippines than in the previous months. A single exception offers in the case of the hurricanes of the second half of September, whose recurring points are from  $5^{\circ}$  to  $8^{\circ}$  farther east. All hurricanes in the Pacific Ocean have as their ultimate destination the northern center of low pressure. The paths of the hurricanes of the China Sea trend more toward the north in proportion as the high pressure area of the continent moves northward, and do this, therefore, up to the end of August and the beginning of September, if, however, the low-pressure area moves toward the south about the beginning of September, then also the paths of these cyclones must follow it. Some of the July hurricanes after recurving follow paths going very nearly northward, they cross over the Yellow Sea and travel toward a small center of low pressure that has developed in Siberia.

The reader who is interested in the movements of the storms of the Asiatic coast may read with profit Bulletin H, Weather Bureau, 1900, on West Indian Hurricanes, by Prof. E. B. Garriott, since the typhoon on the Pacific Ocean and the hurricane of the West Indies are storms of the same general character and have much in common.

During the years 1895, 1896, and 1897 the Weather Bureau office at San Francisco made an attempt to trace the path of a disturbance across the ocean. By means of a large number of ship reports obtained through the courtesy of the Hydrographic Office the approximate path of a disturbance was determined. On the accompanying chart there is shown the path of a disturbance covering a period extending from November 20, 1895, to January 14, 1896. This path was determined by Prof. W. H. Hammon.

It may also be of interest to present a section of the same disturbance in its passage just preceding and following the point of recurvature.

To illustrate the difficulties of forecasting on the Pacific coast owing to the absence of reliable data over the ocean, the accompanying charts showing a forecast official's map with the conditions existing on the morning of January 18, 1896, and the real condition as subsequently determined by plating the observations of ships traversing the North Pacific. It is interesting to notice that a forecast of "rain" for the ensuing thirty-six hours might with the fuller knowledge obtained later have been changed to a long-range forecast covering a period of many days. As a matter of fact, there was no rain reported at San Francisco during the first twelve days of the month of January, 1896; but rain fell on every day from the 18th to the 21st and the total rainfall for this month was 8.14 inches, or nearly double the normal January rainfall.

#### LOW AREAS ON THE PACIFIC COAST.

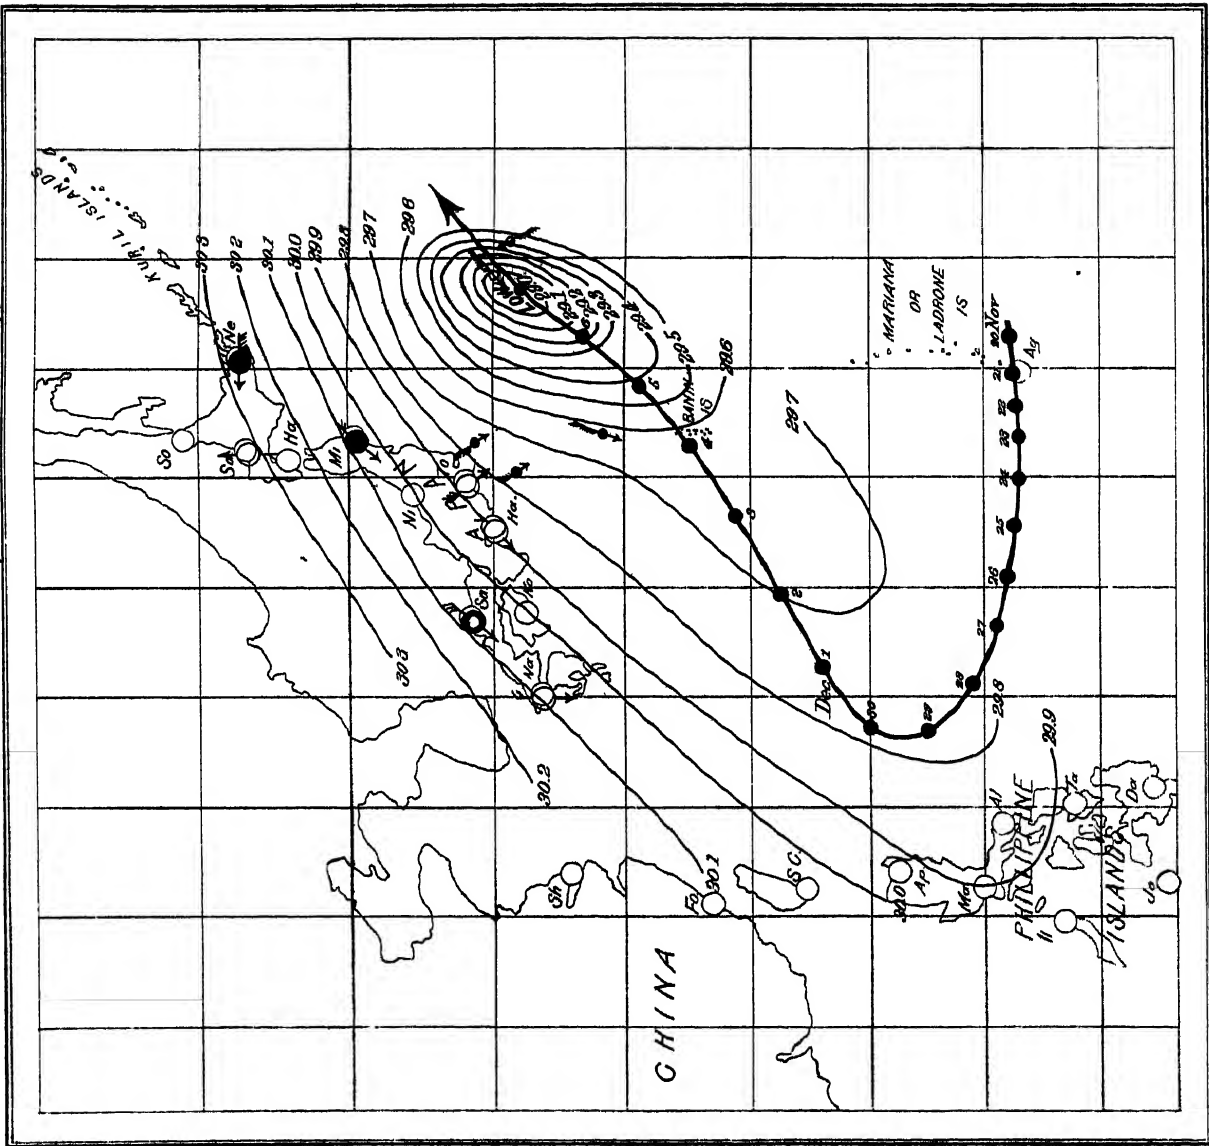

Professor C. Abbe, in *Monthly Weather Review*, November, 1894, states that

The daily chart for the northern hemisphere accompanying the bulletin of international observations in 1875-1887, has long since familiarized the student with the fact that areas of low pressure frequently pursue very long paths for many consecutive days in their circuit around the north temperate regions. Those that start in the equatorial portions of the Atlantic or Pacific, after passing northwest and curving to the southeast, finally move east-northeastward between the forty-fifth and sixty-fifth parallels. Others start in the temperate regions and without moving to the westward or recurving, pursue nearly the whole path in an east-northeast direction. In describing the history of areas of low pressure the authors who have contributed chapters to the successive *Monthly Weather Reviews* for nearly twenty-five years past have usually kept in mind the fact that "low" which first appears in Washington, Oregon, Montana, and Alberta, or British Columbia, have probably originated at some point far to the west, and if occasionally the description of such a storm begins by speaking of it as originating over the North Pacific slope region, this is a slip of the pen which the reader may generally interpret without being misled by it.

On several occasions I have pointed out the fact that the isobars, and therefore the winds of a cyclonoidal distance above the earth's surface, have very little resemblance to the isobars and winds at our level. In fact, the normal isobars at an elevation of 5,000 meters (which represents a surface a little above the summits of the Rocky Mountains) present a grand oval depression whose longest axis extends from the United States toward the north-northwest over the Saskatchewan and the Arctic regions to eastern Siberia. By studying a similar projection of the northern hemisphere we perceive that the whole upper circulation of winds and clouds and the general movement of areas of low pressure and high pressure are related to this distribution of pressure in the upper layers of air. When a storm center moves from Japan to the North Pacific, or from the Indian to our Pacific coast, or from Alaska and Oregon southeastward, or from Texas and Kansas northeastward, it is describing some portion of a circuit about this great upper region of low pressure. It is simply a special whirl gliding about in the maelstrom that occupies one-half of the northern hemisphere. The axis of this oval polar maelstrom probably changes its position with considerable regularity, oscillating slowly to and fro; therefore the paths which the smaller disturbances describe will vary simultaneously with that; sometimes the storms will move far to the south either to America or to Russia in order to circumnavigate the southern extension of the longer axis of the oval; but will thereby diminish in intensity and almost die out. Sometimes a new whirl will start at the southern end of the oval, sometimes all the paths of the low areas will lie on the northern border of the United States and Canadian weather charts because the polar maelstrom has altered its dimensions and locations. Even the great subpermanent areas of low pressure in the North Atlantic and North Pacific are subordinate to the greater area of low pressure at the upper level and the attendant winds.

These remarks were made in discussing the following notes by Professors McAdie, Henry, and Hammon bearing upon the origin and paths of areas of low pressure on the Pacific coast:

A little study of weather types on the Pacific slope makes it plain that certain conditions traverse the country from the Pacific; thus to take at random the month of January, 1895, some of the deep lows that might have been supposed to originate over Manitoba or farther west over Assiniboia, Alberta, and British Columbia did not so originate, but are storms that can be traced distinctly in their onward march from the westward Pacific Ocean northwestward, often recurving and doubling in their paths, but preserving identity. Finding south of them they

Red lines represent available for forecast

Climate of California - Approximate Path of Disturbance  
Traversing Pacific Ocean

march eastward and reach Newfoundland in about one hundred and twenty hours. For example, a storm passed from Sitka to St. Johns between January 12 and 17. This storm did not originate in the Northwest Territory, but clearly came in from the Pacific. Where it did originate we do not know, but it is an error to locate its origin in any of the Northwest territories. And this is probably true of most storms which are said to originate over Athabasca or Saskatchewan. The truth is that storms first come into notice in these localities, but originate elsewhere.

\* \* \* \* \*

The storms of the Pacific coast present a characteristic that is worthy of special study, viz, an apparent oscillation from the ocean to the land, and vice versa; that is to say, the low approaches the coast and partially disappears, reappearing within a period of twelve to thirty-six hours, and continuing this action until the storm finally disappears.

\* \* \* \* \*

During the past two years I have been engaged, during my leisure time, in preparing weather charts of the Pacific Ocean. Some remarkable information has been obtained from these charts. The storms that approach the Pacific coast from the ocean frequently recur several times after touching the coast, the number of oscillations being greater the farther south the storm approaches the coast.

\* \* \* \* \*

Professor Abbe holds that—

The fact that a storm moves southward, ricocheting along the Pacific coast, and probably dying away as it progresses, harmonizes with the general theory of the movement of vortices. If the general distribution of pressure at sea level, and especially at 16,000 feet, is such as to give the storm center a general movement southward or southeastward along the Pacific coast, then the influences of the high mountain land in the interior of California and the plateau lands of Idaho, Nevada, Oregon, Utah, and Arizona are like those of a barrier against which a small atmospheric vortex may strike, only to be reflected several times in succession. A further special influence of these high lands is to furnish descending dry air whose mixture with the moist air of the whirlwind rapidly diminishes the quantity of condensation and the sustaining power of the whole mechanism. The inverse conditions prevail on the east slope of the Rocky Mountains, where, therefore, a whirl once started is apt to increase in all characteristic phenomena. Possibly this process is illustrated by the low area of October 29, 1896, in regard to which Professor McAdie writes: "On Monday, October 28, 1896, a. m., a low, 29.70, with southeast winds, appeared on the Oregon coast. Taking a most unusual course, this storm passed southward and on the morning of the 27th was over central California (San Francisco, 29.56, southeast wind, 1.10 inches rainfall). By 10 o'clock of the same day the storm was moving down the San Joaquin Valley, and heavy rain was falling over southern California. On the morning of the 28th the pressure was 29.78 at El Paso, with rain, and the storm was out of our limits of observation, but just coming into prominence elsewhere."

#### PREVAILING AIR DRIFT AND OCEAN EFFECT.

The prevailing easterly drift of the atmosphere in temperate latitudes, causing the well-known winds from the west, is one of the prime factors in modifying the climate of the coast of California. This coast line, stretching for 10 degrees of latitude, is subjected to a steady indraft of air from the west. In this movement, together with the fact that to the west is the great Pacific Ocean, lies the secret of the difference in temperatures between the Atlantic and the Pacific coasts at places of like latitude. For some years there has been an impression that the milder climate of the Pacific coast was due to a warming influence of the Kuro Siwo, or Japan current. No reliable data exist to support such a belief, and it is quite unlikely that the Japan current plays any important part in modifying the climate of the Pacific coast. The active factors are, as said above, the prevailing easterly drift of the atmosphere and the proximity of the mass of water, a great natural conservator of heat. Further on, the equability of the mean annual temperatures along the coast of California, a distance of nearly 1,000 miles, is discussed, and the area might be extended to include practically the whole of the Pacific coast. One of the most noticeable differences between the climate of the Atlantic and Pacific seabords is found in the trend of the isotherms, those of the Atlantic coast corresponding more or less with the parallels of latitude, while on the Pacific coast the isotherms run more nearly like meridians. Too much emphasis can not be laid upon the effect of these two factors, the easterly drift of the air and the proximity of the ocean in modifying climate. It is probable that if one of these conditions could be reversed and the general movement of the air in these latitudes be from east to west, marked differences in climatic conditions would result, and the Pacific coast might then have a rigorous climate.

## TOPOGRAPHY.

The State of California extends from latitude  $32^{\circ} 40'$  north to  $42^{\circ}$  north with a mean length of something less than 800 miles. The average width of the State is about 200 miles, and it has an area of 155,980 square miles, or 99,827,200 acres. The coast line of the State corresponds in position to that portion of the Atlantic coast extending from Boston to Savannah. Very few rivers, however, empty into the ocean, and in both topography and hydrography there is but little resemblance between the Atlantic and Pacific seaboard. The mountain ranges and other marked physical features play an important rôle in determining local climates, a discussion of which in detail will be given further on. It will not be out of place at this point, though, to call attention to the fact that the highest and lowest lands in the United States, excluding Alaska, are in California. Mount Whitney has an elevation of 4,427 meters (14,522 feet<sup>a</sup>); Mount Shasta, 4,383 meters (14,380 feet<sup>b</sup>); and by referring to the table of elevations<sup>c</sup> it will be seen that we know of at least 43 well-defined mountain peaks with elevations exceeding 3,048 meters (10,000 feet). On the other hand, at Salton and Volcano the depression is 80 meters (263 feet) below sea level. Death Valley, the bed of an old lake about 75 miles long and 6 miles wide, lies in southeastern California, just north of the great Mohave Desert.

A few illustrations showing the diversity of climatic conditions may be of interest. In the Colorado Desert, in the southern portion of the State, shade temperatures as high as  $54^{\circ}$  C. ( $130^{\circ}$  F.) have been recorded. Mean monthly temperatures not much below  $38^{\circ}$  C. ( $100^{\circ}$  F.) frequently occur at Volcano, Salton, Indio, Mammoth Tank, and other places in the great arid regions of southern California, and particularly in the Valley of the Colorado. In the Sierra, just north of Lake Tahoe, temperatures as low as  $-34^{\circ}$  C. ( $-30^{\circ}$  F.) have occurred. During the winter of 1898 a minimum thermometer exposed on one of the high Sierra peaks, Mount Lyell, recorded  $-27^{\circ}$  C. ( $-17^{\circ}$  F.). During the same period the temperature at Bodie reached a minimum of  $-34^{\circ}$  C. ( $-30^{\circ}$  F.).

The mean annual rainfalls, as might be expected, vary from 1 inch to 75 inches. At Mammoth Tank for twenty-three years the mean annual rainfall amounts to 1.81 inches, but here and at other stations there have been years when the rainfall did not exceed a trace.

At Upper Mattole the average annual rainfall is 81 inches, and in individual years rainfalls approximating 100 inches have occurred. The following are some single year rainfalls: Laporte 120 inches, 1896; 101 inches, 1898. Bowman's Dam 119 inches, 1884; 110 inches, 1896. Delta 111 inches, 1889; 100 inches, 1896. Upper Mattole 102 inches, 1896; 101 inches, 1889. Edmonton 102 inches, 1896. Snowfall is confined in general to the central and northern portions of the State and to the mountains of the south. At Summit an annual snowfall of 697 inches has been reported.

The coast line of nearly 1,000 miles shows a difference of but  $10^{\circ}$  F. in the mean annual temperatures of its northern and southern limits. At Eureka the temperature is  $11^{\circ}$  C. ( $51^{\circ}$  F.); at San Francisco,  $13^{\circ}$  C. ( $56^{\circ}$  F.), and at San Diego  $16^{\circ}$  C. ( $61^{\circ}$  F.).

That the coast climates are very equable is shown by the following mean monthly departures. At Eureka the mean January temperature is  $46^{\circ}$ , or a departure of  $5^{\circ}$  from the annual mean; at San Francisco the mean January temperature is  $50^{\circ}$ , or a departure of  $6^{\circ}$  from the annual mean, and at San Diego the mean January temperature is  $54^{\circ}$ , or a departure of  $7^{\circ}$  from the annual mean.

Similarly for the month of July the temperature at Eureka is  $56^{\circ}$ , or  $5^{\circ}$  above the annual, at San Francisco,  $59^{\circ}$ , or  $3^{\circ}$  above the annual, and at San Diego  $68^{\circ}$ , or  $7^{\circ}$  above the annual.

The highest mean annual temperature found in the Colorado Desert is about  $78^{\circ}$ , and the lowest mean annual temperature for stations in the Sierra (Summit, for example) is  $42^{\circ}$ , or a total annual range of  $36^{\circ}$ .

The absolute range as stated above is from  $130^{\circ}$  F. ( $54^{\circ}$  C.) to  $-30^{\circ}$  F. ( $-35^{\circ}$  C.);  $160^{\circ}$  F. ( $89^{\circ}$  C.)

<sup>a</sup> Authority, Langley<sup>b</sup> Authority, U S Geological Survey<sup>c</sup> Authority, The Sierra Club, of San Francisco.

The various elements of sunshine, humidity, wind velocity, and direction vary in different parts of the State to almost as great a degree as rainfall and temperature. Unfortunately continuous and systematic records of these elements are not available for most portions of the State.

The general movement of the air over the State is from the west and north, with strong southeasterly indrafts during the months of November, December, January, and February whenever marked cyclonic disturbances approach the State from the northwest. The general movement of the air in California is decidedly modified and certainly in the lowermost strata almost entirely controlled by the topography. Particularly interesting are the accentuated movements in the great valleys, as shown in the well-known "northers" of May and June. The prevailing westerly winds, wherever allowed access to the interior through gaps in the Coast Range, are greatly intensified and exhibit in both frequency and duration a well-marked relation to the temperatures prevailing in the interior.

One of the most trying climatic conditions prevailing in California is the so-called "norther" or hot north wind which, blowing in the great valleys, is both injurious to ripening crops and irritating to man and beast. May, June, and July are the months of greatest frequency. The condition is as a rule associated with the presence of an area of high pressure over the North Pacific Ocean and a deepening of the usual summer "low" over southeastern California and the Valley of the Colorado. Temperatures of 43° C. (110° F.) or more occur under these conditions. As these brisk northerly winds are very dry and dust laden, ripe fruit and wheat are seriously injured, while human beings and stock suffer greatly because of the irritating effects of the "norther."

In southern California a somewhat similar condition is known as the "Santa Ana." In all of these cases the air has been dynamically heated and dried, either by descensional movement, as when flowing down the mountains or by horizontal movement over superheated plains and deserts.

In the tabulated data which appears further on it will be noticed that the general conditions of temperature and rainfall are greatly modified by the local topography. In California, perhaps more so than in any other part of the habitable earth, a great diversity of climate exists. Within comparatively short distances one may pass from a climate requiring the lightest of summer garments to one requiring overcoats and heavy wraps. A short study of a relief map of California will throw much light on the cause of the great diversity of climate. The subject is discussed in detail in the chapter upon the "Climate of San Francisco," where a marked modification of the normal conditions is undoubtedly affected by the peculiar topography of the locality.

TABLE OF ELEVATIONS EXCEEDING 1,000 METERS (3,281 FEET) IN CALIFORNIA.

Many of the elevations have been supplied by Prof. George Davidson and J. N. Le Conte. For peaks in the High Sierra not included here see supplementary tables.

# CLIMATE OF NORTH AND CENTRAL COAST.

## CLIMATOLOGY OF EUREKA, AND WEATHER CONDITIONS ALONG THE COAST OF NORTHERN CALIFORNIA.

By Mr. A. H. BELL, Observer, Weather Bureau.

The city of Eureka stands on the south shore of Humboldt Bay about 7 miles from the entrance and some 215 miles from San Francisco, latitude north  $40^{\circ} 48'$  and longitude west  $124^{\circ} 11'$ . A few miles east of the city we have the forest-covered foothills of the coast range, while on the west the shore is washed by the Pacific Ocean.

Equable and apparently health-giving is Eureka's climate. Since establishment of the station the highest recorded temperature is  $84^{\circ}$  and the lowest  $20^{\circ}$  above. Fogs and overcast skies prevail at all seasons along the coast. They preserve a uniform temperature and a humid atmosphere, and, to a large extent, determine the character of our industries and productions. In summer, however, cloudless skies and a high temperature are characteristics of the higher latitudes and of the region east of the redwood belt. From October until April is the rainy season, but the wet period is by no means a season of continuous precipitation. Sometimes a rainy season will embrace much pleasant weather. While the prevailing winds are in summer northerly, seldom indeed do they attain the velocity of a gale, usually rising before noon and subsiding before nightfall. These winds are extremely liable to ensue on two or three consecutive days. In winter, on the other hand, the prevailing winds are southeasterly.

Humboldt Bay has a varying width of from half a mile to 4 miles and a length of 14 miles, and possesses a tidal area of about 28 square miles. It lies nearly parallel with the coast, and between it and the ocean there intervenes a sand peninsula with a width of from one-fourth mile to  $1\frac{1}{2}$  miles. So narrow is the entrance and so peculiar are its relations to the body of water within—in other words so completely landlocked is our harbor—that tempestuous weather outside affects it very little.

Some time ago the observer at Eureka arranged with the Humboldt Jetty office for gratuitous daily information respecting the approximate force and direction of the wind and the condition of the ocean adjacent to the bay. To the harbor entrance is a distance of about 7 miles, and the two jetties there extend out into the ocean 7,000 feet. Very often when outside there is a gale with an extremely rough sea; inside there is a calm or a wind from a different direction.

Herewith is a rough sketch of the coast from Cape Mendocino to Patricks Point, a distance of about 40 miles. The coast line is some 10 miles east of a line joining the bluff points of Cape Mendocino and Patricks Point. Still farther to the east the hills form a greater curve, placing the lowlands on which Eureka stands in a protected position from the northwest, east, and southeast, and greatly modifying the conditions prevailing beyond the limits of the area shown in the sketch.

By running a line from the cape to the point one will probably discover that during a severe southeast storm from, say, 20 to 50 miles off coast there is often inside the line or near the coast but a moderate wind. Moreover, a west to northwest wind is much more severe outside than inside this line. The force of southeast winds is no doubt frequently broken by Cape Mendocino and the adjacent hills. Greatly modified in intensity and somewhat deflected, they again approach the coast north of Patricks Point; but in a heavy south wind the resistance of the cape seems inconsiderable. Often in summer, during a moderate wind of 15 miles or more at sea, near the coast and even on the bay it will blow quite strongly. On this coast only seldom does a wind for any great length of time blow directly from the southwest. On its approach to the land it will veer either to the south or to the northwest. During a southeast wind along the coast there is invariably a southwest wind at sea. After a southeast storm a heavy sea from the southwest causes the bay to become rough and extremely dangerous for vessels. Frequently on approaching the coast northwesterly winds will be met by warm currents of air from the land. The result in every instance is fog, and generally a material reduction in the force of the wind. In forecasting southeast storms the high hills east and southeast of this station and extending to Cape Mendocino should be allowed for.

FIG. 5.—Sketch map of Eureka and vicinity.

#### CLIMATE OF SAN FRANCISCO.

On the coast of California there is a city justly famed for the abnormalities of its climate. Overcoats and heavy wraps are worn in midsummer, while the lilies bloom in December. From May until September very little rain falls, yet during this period with clock-like regularity great banks of fog march in every afternoon and cover the bare, brown hills. The city of San Francisco, the gateway to the Orient, as it has been termed, is strangely situated with respect to ocean, bay, mountain, and valley. It may perhaps be said of this city that nowhere else can such a strange mixture of marine and continental climates be found. The topography is such that marked contrasts can be found within comparatively short distances. Certainly the climatologist finds in the vicinity of San Francisco so many climatic anomalies that he feels as if he

were in fact present in a great natural aero-physical laboratory where daily experiments were being performed on a large scale. In building this meteorological laboratory at San Francisco nature also provided seats wherefrom we can obtain excellent views of the experiments while in progress. From the Weather Bureau station on Mount Tamalpais—elevation of station, 2,373 feet—one looks down on the broad expanse of the Pacific, nearly 20,000,000 square miles of water, to the north, west, and south. From the open roadstead of Drakes Bay the eye passes over the Sausalito hills to the headlands of Points Bonita and Lobos, marking the entrance to the Golden Gate. This passage plays an important rôle in connection with the winds, temperatures, and fogs of the San Francisco Bay region. At mean tide the area of San Francisco Bay is about 450 square miles.

Far on the eastern horizon, especially on clear winter days, the snow of the Sierra—155 miles distant—can be seen glistening. These mountains vary in height from 8,000 to 14,000 feet.

Extending from the slopes of the Sierra to the Coast Range is a great basin 500 miles long and about 50 wide. The Sacramento and San Joaquin rivers, flowing through this basin, unite in Suisun Bay. This great inland basin, surrounded by mountain walls, is connected with the Pacific Ocean by the gate at San Francisco, San Francisco Bay, San Pablo Bay, Carquinez Straits, and Suisun Bay. Here, then, is an aero-physical laboratory par excellence. Now for the results.

When a native of San Francisco is asked which is the coldest month of the year, he is generally at a loss for an answer; and if asked which is the warmest he may say November. This confusion arises from the comparatively small range of temperature. The mean annual temperature, as determined from the records of the Weather Bureau for thirty-one years is 56.1° F. May and November have practically the same temperature. The warmest month is September, 60.8°; the coldest, January, 50.2°. The other months have mean temperatures as follows: February, 52°; March, 54°; April, 55°; May, 57°; June, July, and August, 59°; October, 60°; November, 56°; December, 52°.

The highest temperature ever recorded at San Francisco was 100°, on June 29, 1891, and the lowest 29°, on January 15, 1888. Abnormally warm and cold periods last, as a rule, about three days. The mean of the three consecutive warmest days at San Francisco has never exceeded 76.3°. A period of warm weather during the summer months is, as a rule, brought to a close about the evening of the third day with strong west winds, dense fog, and temperatures ranging from 49° to 54°. The mean of the three consecutive coldest days was 40.7°. The greatest daily range of temperature was 43°, on June 29, 1891. This was the date when the temperature reached 100°. The range of temperature was from 100° to 57°. The morning was calm and very warm, while at 5 p. m. the temperature was 80° and next morning 74°.

In the past thirty years the number of days on which snow has fallen can be counted on the ten fingers. Thunderstorms likewise are infrequent, but not altogether unknown. Earthquakes, meaning by this all slight shocks and tremors, average about 7 per annum. Very little damage has been done by earthquakes during the past fifty years.

The people in San Francisco have long realized that winter and summer are purely relative terms. Thus at any of the ferries on a midsummer day one can see summer fabrics worn with heavy wraps, and it is not unusual to see white duck and sealskin in combination. Visitors to the city should by all means wear heavy wraps or overcoats during the summer afternoon.

The experiments of the observers of the Weather Bureau during the past two years with kites have thrown much light upon the causes of the climatic abnormalities experienced at San Francisco; and, among other things, it has become evident that in summer as we ascend from the ground the temperature rises. For each 155 feet of elevation the temperature is 1° F. warmer, and so on any of the hills or mountains in the vicinity of San Francisco one can find with very little effort the climate best suited for him. In other words, the citizen of the San Francisco Bay section can regulate the temperature to suit himself, having a choice between these limits: 55° at sea level and 85° at 2,000 feet above.

With regard to rainfall, during the summer months, San Francisco is practically rainless. By referring to the accompanying charts it will be seen that in June, July, August, and September showers are very rare. The average rainfall is about 23 inches, and most of this falls during the months of November, December, January, February, and March. Looking over the records of the past fifty years we find that the year 1898 had but 9.31 inches, while in 1883 there was 38.82 inches. In 1861 there was 38.51 inches.

## SEASONAL RAINFALL.

The annual rainfalls do not, however, fairly represent the amount of rainfall determining crop yield. Both with fruits and grains it is the seasonal rainfall rather than the annual which is to be considered. In the wheat fields summer fallowing is resorted to chiefly for the reason that the rain of two seasons can be utilized. As may be seen by the tables of annual and seasonal rainfall, published in following pages, the amounts during the growing season vary from the totals for the calendar year; thus, in 1889-90 the seasonal rainfall was 45.85 inches. The annual rainfall for 1890 was but 25.43 inches, an unusually heavy rainfall in December, 1889, having contributed to materially increase the seasonal amount.

Frequency as well as intensity should also be taken into account in considering the relation of rainfall and crops.

## SOME MAXIMUM AND MINIMUM TEMPERATURES.

The following tables showing the temperature when the thermometer registered 80° or above and 32° or below (Fahrenheit), with dates of same, were kindly furnished by Mr. Thomas Tennent. The thermometers used by Mr. Tennent were self-registering instruments purchased from McAllister & Co., of Philadelphia, Pa., and brought out by him in 1849; they were tested and found to be correct. The thermometers were exposed on the north side of a building, on supports about 10 inches from the walls and about 6 feet above the ground. The readings were made by Mr. Tennent personally, and cover the period from September 1, 1849, to December 31, 1871:

## NOTES FROM THE RECORD OF G. H. GIBBONS, M D

1847.

[From the California Star, San Francisco]

*January 19* —Ice nearly one-fourth inch thick—the first of the season, said to be a cold winter*February 19* —Heavy rains still continue at regular intervals of four to eight days Already more rain this season than in last three years*April 3* —A number of heavy rains in last six days. Dry weather for four or five weeks preceding Dry weather appears to have followed*May 8*.—During the past week a succession of showers, sufficient to moisten the earth—the annual “May rains,” none to come after San Joaquin country flooded, unusual amount of rain on the mountains in winter*May 22* —Several light showers during past week*July 2*.—A light but refreshing shower, barely sufficient to render the dust adhesive, a promise of more.*August 21* —Cold winds and heavy fogs throughout the week*August 28* —A heavy shower of rain in evening, with thunder and lightning, extending some miles back*September 18* —A week of hot and calm weather, 92° in shade*September 25*.—Sou'westers, sea fogs, etc ; “cool to overcoating” this week*October 20* —A furious norther, lasting till evening*October 30*.—Weather dubious, inclining to “heavy wet”*November 6* —Winter fairly closed in The past week cold and disagreeable, with drenching rains and cold winds For a few days no locomotion allowed.

1848

*February 26* —Rain fell abundantly the past week, and snow on the mountains.*March 18*.—Heavy rains during the week Several weeks preceding the weather was delightful, 63°.*April 1* —Rains have been abundant

1849.

[San Francisco Whig of September 3, 1852]

*September 19*.—Thunderstorm on Mokelumne River

[From the Alta-California, April 17, 1850]

The first southeast blow was on November 13 and the last in March, 7 southeast blows in that period, and seventy-one days rain in those one hundred and thirty-nine days. Mean barometer 29.12; temperature 57°

1850.

[From the San Francisco Herald]

*September 10* —Heavy rain above Marysville*September 11*.—Shower at Marysville*September 12* —First rain of season, light shower at 6 a. m. at San Francisco.*September 15* —Gentle rain most of day at San Francisco*September 20* —Shower last night*September 20 and 22* —Rain on Tuolumne, great flood*September 21* —Moist and hazy. Much rain during day.*September 22*.—Bright and warm*September 23*.—Rain at 2 p. m. and all the evening*October* —No rain noted during month.*November 19* —Rain at times, began in morning, slight showers frequent through the day and night Severe gale from southeast in p. m., blew down Presbyterian church on Stockton street and damaged shipping*November 22*.—Rain storm. Price of carting raised from \$1 and \$1.50 to \$2 and \$2.50 from mud.*November 23* —Calaboose inundated 1 foot during night.

The tables of monthly and seasonal rainfalls for San Francisco are given on page 9.

## DATES OF SNOWFALL IN SAN FRANCISCO SINCE MARCH 1, 1871

*January 21, 1876* —Light snow fell for ten minutes  
*December 31, 1882* —Heavy snow fell from 11 30 a m to 4 20 p m , amount, 3.5 inches  
*February 6, 1883* —A few flakes of snow fell during the day  
*February 7, 1884* —Snow fell at intervals during the day, depth varying from 1 to 2 inches  
*February 5, 1887* —Snow fell during the day; depth at office, 3 7 inches, while in the western portion of the city it was fully 7 inches deep.  
*January 4, 1888* —A few flakes of snow fell during the day  
*January 16, 1888* —Light snow fell to the depth of 0 1 inch.  
*March 2, 1894* —A few flakes of snow fell during the day.  
*March 2, 1896* —Snow mixed with rain fell at intervals during the day  
*March 3, 1896* —Heavy snow fell during the night; depth at office at 8 a. m , 1 inch.  
*February 3, 1903* —Snow and rain, large flakes, 11 16 to 11 20 a m.

## THE GREAT RAINSTORM OF 1866.

Mr. L. J. Le Conte, C. E., of Oakland, has kindly furnished the following relative to the great rainstorm in this city on the 19th and 20th of December, 1866:

Our profession is interested in maximum rainfall in twenty-four hours. I inclose a copy of the record of the memorable rainfall of December 19 and 20, 1866, which is given in hourly subdivisions. The monthly rainfall was also the maximum on record—15 16 inches—while at Sacramento the record was 12.90 inches. I think this was published in full in the Evening Bulletin in December, 1885.

Following is the record referred to:

Inches	Inches
December 19—11 45 a m to 4 45 p m ..... 1 97	December 20—1 a. m to 8.15 a m ..... 1 47
December 19—4 45 p m to 7 45 p. m ..... 2 27	
December 19—7.45 p. m to 9 50 p m ..... 0 85	Total in 21 hours ..... 7 76
December 19—9 50 p m to 1 a m ..... 1 20	

FIG. 6.—Monthly curves of hourly wind velocities.

FIG. 7.—Hourly wind velocities at San Francisco.

FIG. 8.—Mean relative humidity—upper, 5 a. m., lower, 5 p. m.

FIG. 9.—Percentage annual rainfall each month.—From Bulletin D, by A. J. Henry.

RAINFALL (INCHES AND HUNDREDTHS) AS MEASURED BY JOHN PETTEE, JANUARY 1, 1865, TO MARCH 19, 1902

[In this record the day commences at about 7 a m on the date mentioned and ends on the succeeding day at about 7 a m ]

# CLIMATE OF SOUTHERN COAST.

## SAN LUIS OBISPO.

Data by Mr. JOHN R. WILLIAMS, Observer, U. S. Weather Bureau

San Luis Obispo is situated in latitude 35° 18' north, longitude 120° 39' west. It is distant from Port Harford, or the Pacific Ocean, about 10 miles. A range of low hills intervenes between the coast and the city. The average elevation of the San Luis Range to the west is about 1,000 feet. The San Luis Valley southwest of the city has a general elevation of less than 150 feet. Directly west of the city, at a distance of about 1 mile, is a large hill (Cerro San Luis Obispo), elevation 1,292 feet. East of the city are the foothills of the Santa Lucia Range, varying in elevation from 1,700 feet 2 miles east of the city to 2,830 feet 5 miles east. The general elevation of the city is about 200 feet above sea level. The elevation of the Weather Bureau office is 201 feet.

Owing to the topography, the range of temperature is large. Daily ranges of 40° or more are not infrequent. The lowest temperature<sup>a</sup> recorded is 24° and the highest 106°. The mean annual temperature is 58.9°. The mean annual rainfall, based upon Weather Bureau records covering a period of six years, is 17.22 inches.

The following table, showing the seasonal rainfall at San Luis Obispo for the past twenty-eight years, is taken from the pamphlet "On the climate and wealth of San Luis Obispo County," by Myron Angel:

## SANTA BARBARA

Santa Barbara is situated in latitude  $34^{\circ} 23'$  north and longitude  $119^{\circ} 40'$  west. In considering the entire coast line of California from Point St. George to San Diego one is struck by several marked changes of direction. The most noticeable bend occurs at Point Arguello, where the coast runs nearly due east to Santa Barbara and there bends southeast again with a short stretch running east and west between Point Dume and Santa Monica. Santa Barbara occupies a central position on that part of the coast of California which distinctively faces southward. Santa Barbara Channel, with a depth of water varying from 25 to 365 fathoms, lies between the mainland and San Miguel Island, Santa Rosa Island, Santa Cruz Island, and Anacapa Island. The Santa Ynez Mountains traverse this section of California running east and west, and embrace a number of valleys, the Santa Maria, Lompoc, Los Alamos, and Santa Ynez in the north and the Santa Barbara in the south. The city itself lies encircled by foothills except to the south, where it fronts the sea. Because of these topographical features the climatic conditions approach the ideal.

For many years temperature and rainfall records were maintained by the late Mr. Hugh D. Vail. At the request of the Santa Barbara Chamber of Commerce, Dr. C. Max Richter has carefully gone over these records and compiled the following data, covering a period of fifteen years for Santa Barbara. The records for a period of three years maintained at his own station—Pine Crest, Santa Barbara foothills—are also given. To illustrate the differences in rainfall existing within short distances where topographical conditions are so varied as they are here, Dr. Richter calls attention to the rainfall at Santa Barbara during the month of October, 1901. 2.42 inches of rain fell on October 26, while at Pine Crest, 2 miles away, 2.86 inches fell on the 26th, 0.66 of an inch on the 27th, and 0.03 inch on the 28th. The rainfall at the upper station, elevation 850 feet, exceeded that at the lower station, elevation 100 feet, in the ratio of 3 to 2.

The highest temperature recorded at Santa Barbara is  $107^{\circ}$  and the lowest  $28.5^{\circ}$ . The temperatures of winter and spring months approximate  $56^{\circ}$ ; summer and fall months  $63^{\circ}$ . The annual mean temperature is about  $60^{\circ}$ .

## THE CLIMATE OF SANTA BARBARA.

[By Dr. C. M. Richter.]

## LOS ANGELES.

By MR. G. E. FRANKLIN, Local Forecaster.

Los Angeles City is located in a valley of the same name, 18 miles from the Pacific Ocean. Its chief topographical feature is a range of hills of moderate elevation on the western side, with a general trend north to south, which separates it from the Cahuenga Valley, that extends to the ocean on the west. The eastern side is slightly undulating and broadens out into the Los Angeles Valley, which reaches the ocean on the south.

A great variety of climate may be found within a small radius. A traveler may start from the ocean at Santa Monica, Redondo, Long Beach, or other seaside places in the morning and within two or three hours' ride by rail and cable railway attain an altitude of 2,000 feet, whence by trails he can ascend to 6,000 feet.

The rain storms do not last usually more than two or three days at a time; occasionally they continue a week, and are followed by periods of fine weather lasting two or three weeks. An average of three hundred and seventeen clear days, or days when the sun is but partly obscured, is the record for the past twenty-three and a half years; the sunshine averages 75 per cent. The first rains wash the atmosphere of the summer's dust, when the sky becomes beautifully clear; the later rains are heavier and snow falls in the mountains, though a light fall may occur with the first rain.

The prevailing wind is west, which, coming from the ocean, causes the humidity to average quite high. The nights as a rule are cool and damp and the days warm and dry, or moderately so. Morning fogs are frequent from spring to autumn, but they disappear in the early forenoon.

During heavy fogs the air is so saturated with moisture that it is not uncommon to find a precipitation of one-hundredth of an inch in the gauge. On the other hand, the humidity falls as low as 9 per cent during "northers," which occasionally occur in the summer and autumn months. These "northers" last from one to five days, usually three, and are accompanied by high temperature, which is so modified by the dryness of the air as to be neither oppressive nor debilitating.

In consulting the accompanying temperature tables it should be borne in mind that the instruments from which the data were obtained were located on roofs of buildings, 60 to 70 feet above ground, exposed in standard shelters and above the stratum of colder air which settles on low ground. The temperature so obtained is appreciably different from that on the surface, lower maxima and higher minima resulting. For the above reasons the temperature seldom falls to freezing or below at the Weather Bureau station, while in the low grounds it frequently reaches 32° or several degrees below in winter, when a much higher temperature obtains at the station; this corresponds to the foothill belts, where frost seldom if ever happens. Frost occurs in the low sections of the city when in the hill portions there is not the least trace, and where delicate flowers, such as calla lillies, may be seen in full flower.

The following table shows the actual and possible number of hours of sunshine and percentages of each month at Los Angeles, Cal., from October, 1896, to December, 1900, inclusive. The record is derived from the Weather Bureau photographic sunshine recorder, which forms a portion of the standard equipment of instruments at the Los Angeles Station.

## SAN DIEGO, CAL.

By Mr. FORD A. CARPENTER, Observer, Weather Bureau.

Four elements enter into a consideration of the climate of San Diego. Named according to their importance, they are as follows: (1) Distance from the northern storm tracks, and the southern storms of the lower California coast; (2) proximity to the ocean on the west; (3) the mountains in the east; and (4) the great Colorado Desert still farther east. The number of the northern areas of low pressure sufficiently great and moving far enough south to exert an influence at the latitude of San Diego are comparatively few; not one-tenth of these "lows" have an appreciable effect on the climate. The storms from the south ("Sonoras," as they are locally known) have but little energy, and probably average two a year. As is the case in all marine climates, the ocean exerts by far the most powerful effect. This is noticed in the slight daily variation in temperature and the absence of either cold or hot weather. The average daily change in temperature from day to day is 2 degrees, and the extremes in temperature from a record of thirty years are 101° and 32°. The temperature has exceeded 90° nineteen times in thirty years, or on an average of about twice every three years. Four times in the history of the station has the temperature touched 32°, but has never fallen lower. Four killing frosts have occurred in San Diego since the establishment of the station, but aside from blackening tender shoots and killing delicate flowers, no damage was done.

The desert winds are responsible for temperatures above 90°, and they are therefore accompanied by extremely low humidity. Records of humidity below 10 per cent are not uncommon during the two or three hours' duration of the desert wind. Three per cent is the lowest relative humidity ever recorded at this station. As the sea breeze is stronger than the desert wind, the highest point reached, whenever the temperature is above 90°, usually occurs about 11 a. m. At this time the sea breeze overcomes the land breeze and the temperature drops to the normal.

Nothing so clearly illustrates the strictly local character of the climate of San Diego as the humidity. While the mean annual relative humidity is 78 per cent at the Weather Bureau station, 2 miles north and at an increase of 200 feet in elevation, the humidity decreases 15 per cent. Five miles away, and at an elevation of 300 feet, there is a further decrease of 5 per cent. The temperature is of course proportionately higher.

The maximum amount of sunshine occurs in November and the minimum in May and June, the winters being usually bright and warm and the summers cloudy and cool. The photographic sunshine recorder was installed in 1890, and this ten years' record shows an average of four days each year without sunshine.

There is a difference of about 1 mile an hour in the average hourly velocity of the wind between the summer and the winter months; the mean annual hourly velocity is 5 miles. While the wind blows from every point of the compass during a normal day, the land breeze is very light, averaging about 3 miles per hour, reaching its lowest velocity just before the sea breeze starts in. The records show that there is an average velocity of from 6 to 9 miles from 10 a. m. to 6 p. m. During the summer a velocity of 6 miles is attained at 9 a. m., increasing to 10 miles at 2 p. m., reaching 6 miles at 7 p. m. The winter months have about five hours of wind over 6 miles, beginning shortly after noon. Winds from 25 to 30 miles per hour occur infrequently, the average annual number being two. Winds of from 31 to 40 miles have an average of less than one a year. The highest velocity ever attained was 40 miles from the northwest, in February, 1878.

The record of meteorological observations began in July, 1849, and was made entirely by officials of the Government. The Army and Coast Survey kept up the record until the establishment of this station by the Signal Service, November 1, 1871. Since this date the location of the observing office has been changed a number of times, but the different places have all been within a radius of a few blocks. The office is now in the Keating building, corner Fifth and F streets. The instruments have elevations as follows: Thermometer, 94 feet; rain gauge, 86 feet; anemometer, 102 feet.

# CLIMATOLOGY OF THE GREAT VALLEY.

## RED BLUFF.

Data by Mr. MAURICE CONNELL, Observer, Weather Bureau.

Red Bluff is the county seat of Tehama County, at the northern end of the Sacramento Valley. The city is situated on the western bank of the Sacramento River, the average elevation above sea level being 309 feet, and is in latitude  $40^{\circ} 10'$  north, longitude  $122^{\circ} 14'$  west. The land slopes gently to the river, and within a radius of 5 miles the country is comparatively flat. The general movement of the air is from the north and northeast into the valley from the mountains on the north and east. During the summer months, however, there is a well-marked southerly movement of the air, which is in part due to the strong westerly indraft through the Golden Gate and its subsequent deflection northward through the valley. The highest temperature recorded is  $114^{\circ}$  and the lowest  $18^{\circ}$ . The average annual precipitation is 25.56 inches.

## SACRAMENTO.

Excellent records of temperature and rainfall are available for the city of Sacramento. This city may in a climatological sense be called the most representative city of the great valley. San Francisco, Sacramento, and Stockton form as it were the three central points of the bay and valley district. It will be noticed that the mean annual temperatures are respectively about 56°, 60°, and 60°. In other words the valley cities have a mean annual temperature about 4° higher than the coast city has. In January the mean temperature of the interior cities is nearly 4° below that of San Francisco. In March it is slightly above. In April nearly 4° above, which increase continues until October. During July there is a difference of nearly 15°. While the annual rainfall at San Francisco is 23 inches, that at Sacramento is 19.21 inches, and at Stockton 15.54 inches. There is thus a gradual decrease in the rainfall from the coast inland. December is the month of heaviest rainfall at all stations and August the month of least precipitation. With regard to the seasonal rainfall it may be stated that years in which the rainfall is well distributed, particularly where good rains fall in March and April, are years of large wheat yields.

## CLIMATOLOGY OF CALIFORNIA.

The following data, showing the temperature and weather conditions of Sacramento, were compiled by Mr. J. A. Barwick, of the Weather Bureau, from the records of Dr. T. A. Logan; Dr. F. M. Hatch; Mr. S. H. Gerrish, and the Weather Bureau.

MEAN MONTHLY AND ANNUAL TEMPERATURE (DEGREES FAHRENHEIT)

e No killing frost, coldest February 8, 1900

Dates of snowfall in Sacramento, and the amount precipitated.—January 29, 1862, 0 75 of an inch. January 12, 1868, 1 62 inches December 3, 1873, 6 inches April 5, 1875, a trace, enough to whiten the ground before it melted. This was the coldest April ever known A very light trace on January 13, 1879 January 26, 1880, estimated about 0 25 of an inch, it mostly melted as it fell February 17 and 18, 1882, trace. December 31, 1882, estimated about 4 inches, measured 1 50 inches actual measurement. February 1 and 6, 1883, a very light fall of snow. January 4, 1888, 2 89 inches January 5, 1888, 3 inches The snow that fell on the 5th was very damp, and packed hard, if it had been as light as that on the 4th, I think we would have had over 6 inches January 16, 1888, a trace. January 12 and 21, 1890, a few flakes of snow, melting as fast as they fell March 2, 1896, during the rain the air was filled with large flakes of snow for ten minutes, which melted as it fell A few flakes of snow fell February 2, 1899 Mr. Gerrish states that the frost of April 4, 1901, did more damage than the frost on February 11, 1901, when the temperature fell to 32°.

## MONTHLY, ANNUAL, AND SEASONAL PRECIPITATION (INCHES AND HUNDREDTHS).

By Mr J. P. BOLTON, Observer, Weather Bureau

During the period from October to May, comprising the wet season, Fresno County is favored with well-distributed rains at irregular intervals, aggregating for the season an average of about 10.12 inches. The greatest number of consecutive days with rain was eight, in January, 1895, the greatest amount recorded in any twenty-four consecutive hours being 2.10 inches—December 29 to 30, 1891.

A dry season prevails over this section during the period from May to September.

The highest temperature ever recorded at Fresno was 114°, on July 1, 1891; the lowest was 20° above zero, on January 17, 1888.

## CLIMATE OF SANTA CLARA VALLEY.

The Santa Clara Valley lies between the Santa Cruz Mountains on the west and the foothills of the Coast Range on the east. In some respects it is an ideal valley in which to study the general movements of the air and the modifications of the same due to topography. We are fortunately able to discuss the principal climatic factors for the following stations: Menlo Park, San Mateo, San Jose, and the Lick Observatory at Mount Hamilton. Mount Tamalpais and San Francisco should be added to the list for a proper understanding of the air movement through the valley. As has been stated before, the prevailing westerly winds are strongly intensified at the Golden Gate, and the whole effect of the topography is to force the air down the valley. Some interesting relations showing the effect of topography upon rainfall become apparent. The mountain stations show a much larger rainfall. On Tamalpais the rainfall exceeds that of San Francisco in the ratio of 3 to 2, and at Mount Hamilton the rainfall exceeds that of San Jose in the ratio of 2 to 1. The gradual increase in rainfall even in so short a distance as 50 miles is also apparent. The mean annual rainfall at San Jose is 14.88 inches, at Menlo Park 16.43 inches, at San Mateo 20.71 inches, and at San Francisco 23 inches. In other words, within a distance of 50 miles, from San Jose to San Francisco, we find an increase of nearly 8 inches in rainfall, and this increase is nearly in proportion to the distance from San Francisco.

The following comparative data for the six stations for a period of three years serve excellently to show the general features of the climate of the Santa Clara Valley:

The mean annual temperature for three years at Mount Tamalpais is  $55.3^{\circ}$ , and for San Francisco for the same period is  $55.3^{\circ}$ , which is practically the temperature of the Pacific Ocean near the Golden Gate. The mean annual temperature for San Jose for a period of twenty-six years is  $58^{\circ}$ , and for San Francisco  $56^{\circ}$ . The mean annual temperature on Mount Hamilton is  $52^{\circ}$ . At both of the mountain stations there is a well-marked seasonal curve of temperature. Comparing the mean annual temperatures it would appear that from sea level to 1,000 meters elevation the fall in temperature is  $1.5^{\circ}$  C. In January the mean temperatures are, from sea level up,  $10.1^{\circ}$ ,  $7.4^{\circ}$ , and  $5.5^{\circ}$  C., or there is a vertical gradient of  $1^{\circ}$  fall for 260 meters. But in July this gradient is inverted, and the temperatures run from sea level upward as follows:  $13.7^{\circ}$ ,  $21.3^{\circ}$ , and  $22^{\circ}$  C., or at the rate of  $1^{\circ}$  rise for 44 meters. These temperature inversions are due to the water vapor carried by the winds through the Gate from the Pacific and down the valleys. Under normal conditions ascending air cools at the rate of  $1^{\circ}$  C. for 100 meters of ascent. But our experiments at Mount Tamalpais show that often the temperature contrasts are more marked than the general averages quoted above would indicate. Sea-level temperatures ( $12^{\circ}$  or  $13^{\circ}$  C.) and fog often prevail to the 500-meter level, while at 700 meters clear weather with temperatures of  $25^{\circ}$  or  $26^{\circ}$  C. prevail. For example, on July 15, 1900, at 5 p. m., the temperature at San Francisco was  $11^{\circ}$  C. ( $52^{\circ}$  F.), at Point Reyes  $13^{\circ}$  C. ( $55^{\circ}$  F.), and at Mount Tamalpais  $27^{\circ}$  C. ( $80^{\circ}$  F.). It is also interesting to note that the temperatures at Red Bluff, Sacramento, and Fresno were respectively  $39^{\circ}$  C. ( $102^{\circ}$  F.),  $33^{\circ}$  C. ( $92^{\circ}$  F.), and  $38^{\circ}$  C. ( $100^{\circ}$  F.). The mean of three temperature values at different points in fog gave a temperature of  $10^{\circ}$  C. or  $50^{\circ}$  F. as the temperature of condensation or the dew-point. The maximum weight of the water vapor per cubic foot at this temperature is 4.076 grains.

## MENLO PARK

Menlo Park is situated about 25 miles in an air line south of San Francisco, in latitude  $37^{\circ} 27'$  north, longitude  $122^{\circ} 11'$  west. To the east lies the southern portion of San Francisco Bay, about 4 miles wide. The average elevation is between 50 and 60 feet. About 3 miles to the west the land rises, varying in elevation from 100 to 500 feet. To the southwest, at a distance of about 8 miles, the Montara Mountains attain heights of from 1,000 to 2,000 feet.

The mean annual temperature, based upon records covering a period of twenty-three years, is  $57.7^{\circ}$ , which is practically the same temperature as that of San Jose and about  $2^{\circ}$  warmer than that of San Francisco. The coldest month is January, with a mean temperature of  $47.3^{\circ}$ , and the warmest is July, with a mean temperature of  $67.7^{\circ}$ . The highest temperature recorded is  $106^{\circ}$ , in June, 1891, and the lowest  $20^{\circ}$ , in December, 1879, and January, 1888. Reliable frost data are not available.

The mean annual rainfall, based upon records covering twenty-three years, is 16.43 inches, or nearly 2 inches more than at San Jose and 7 inches less than at San Francisco. With the single exception of a heavy rainfall in 1886, no rain has fallen in July. December is the month of heaviest rainfall, and more than half of the annual rainfall occurs in the months of December, January, February, and March. During the past twenty-three years there have been but two years when the rainfall did not exceed 10 inches. In 1878 and 1898 the annual rainfall was but slightly above 9 inches. There have been five years when the annual rainfall exceeded 20 inches. In 1889 the total rainfall for the year was 26.90 inches.

## SAN MATEO.

[Data from records of Southern Pacific Railway Company.]

San Mateo is situated in latitude  $37^{\circ} 34'$  north, longitude  $122^{\circ} 19'$  west, about 14 miles in an air line south and slightly east of San Francisco. By railroad the distance is about 22 miles. The elevation is about 22 feet above sea level. To the north and east, at a distance of about 1 mile, are the waters of San Francisco Bay, while to the west, stretching northwest to southeast, are the hills of the Buriburi ridge, with elevations varying from 200 to 600 feet.

The mean annual temperature, based upon records covering a period of twenty-seven years, from 1874 to 1900, inclusive, is  $57.6^{\circ}$ , which, it is interesting to notice, is almost that of Menlo Park,  $57.7^{\circ}$ , and practically the same as that of San Jose. The coldest month is January, with a mean temperature of  $47.9^{\circ}$ , and the warmest is July,  $65.4^{\circ}$ . It will be noticed that July is  $2.3^{\circ}$  cooler than at Menlo Park, and  $1.8^{\circ}$  cooler than at San Jose, but  $6.6^{\circ}$  warmer than at San Francisco. The highest temperature recorded is  $100^{\circ}$ , in May, 1887, and the lowest  $25^{\circ}$ , on several dates. Reliable frost data are not available.

The mean annual rainfall is 20.71 inches, or about 4 inches more than at Menlo Park. With the single exception of a rain in 1886, no rain has fallen during the month of July. The month of heaviest rainfall is January, and in this respect San Mateo differs from other points in the valley, December being the month of heaviest rainfall elsewhere. In the past twenty-seven years there has been but one year when the rainfall did not exceed 10 inches. In 1877 but 8 inches of rain fell. There have been fourteen years when the annual rainfall exceeded 20 inches. In 1894 over 34 inches fell. The greatest monthly precipitation amounted to 12.44 inches, during December, 1889.

## SAN JOSE.

San Jose, the county seat of Santa Clara County, lies about 50 miles southeast of San Francisco, or about 8 miles southeast of the lower end of San Francisco Bay.

The elevation of San Jose varies from about 80 to 100 feet above sea level, and an elevation of 400 feet, except immediately south of the city, is not reached within a radius of 5 miles. Within 10 miles elevations ranging from 400 to 2,000 feet are reached. The general movement of the air is from the northwest. The influence of the Golden Gate, with its strong indraft of cool, fog-laden air is noticeable throughout the Santa Clara Valley. The valley, however, is somewhat sheltered from the strong westerly surface currents prevalent on the coast of California. Summer fogs, especially when low, do not drift inland, being as a rule barred by the mountains. High fogs occasionally blow over and down the mountain sides. Low winter fogs are not infrequent, and are probably due as elsewhere to a settling of the cooler air in the lowlands.

The mean annual temperature, based upon records extending over a period of twenty-six years, is 58°. The coldest month is January, with a mean temperature of 48°, and the warmest is July, 66.7°.

The highest temperature recorded within this period of twenty-six years was 104°. The temperature has reached 100° but five times. The lowest temperature was 18°, or an absolute range of 86°. No frost data are available.

The mean annual rainfall for twenty-six years is 14.88 inches. About half of this falls in December, January, and February. July and August are practically rainless, as only three times during July and once in August has rain fallen to an appreciable extent. The rain has exceeded 20 inches in four years and less than 10 has fallen in four years. The driest year was 1875, with 5.51 inches, and the year with greatest rainfall was 1889, with 25.55 inches. The greatest monthly rainfall was 10.55 in December, 1889.

## MOUNT HAMILTON.

[Lick Observatory]

The director of the Lick Observatory, Dr. Wallace W. Campbell, has kindly placed at the disposal of the Weather Bureau the observations made at Mount Hamilton by different members of the observatory staff from 1888 to 1900. The following named gentlemen have at various times acted as observers: Charles B. Hill, A. J. Burnham, H. K. Curtis, A. O. Leuschner, A. L. Colton, C. D. Perrine, R. G. Aitken, W. H. Wright, H. K. Palmer, E. F. Coddington, and A. J. Cloud.

The observatory is situated on Mount Hamilton, a peak in the Coast Range, in Santa Clara County. The elevation of the station is 1,283 meters (4,209 feet) above sea level. The observatory is situated in latitude  $37^{\circ} 20' 25.6''$  north, longitude  $121^{\circ} 38' 4.22''$  west. The mountain is about 14 miles in an air line directly east of the city of San Jose.

The records for temperature at Mount Hamilton cover a period of twelve years and for precipitation twenty years. The mean annual temperature is  $52^{\circ}$ . The coldest month is January, with a mean temperature of  $39.7^{\circ}$ , and the warmest month is July, with a mean temperature of  $69.4^{\circ}$ . The highest temperature recorded is  $94^{\circ}$ , on July 1, 1891, and the lowest  $13^{\circ}$ , on February 4, 1899.

Rain falls in every month of the year, but in July and August the showers are light and infrequent. The mean annual precipitation is 32 inches, which, it is interesting to notice, is more than double that of San Jose, where the mean, based upon records covering twenty-six years, is but 14.88 inches. The ratio of the rainfall on the mountain to that in the valley appears to be fairly constant for all months in the year. December is the month of heaviest precipitation on the mountain. More than half of the annual rainfall occurs in the four months of December, January, February, and March. The annual precipitation has exceeded 30 inches during eight years of the twenty, and has fallen below 20 inches during two years. These dry years were 1885, when the rainfall amounted to but 18.23 inches, and the memorable 1898, when but 17.11 inches fell. The years of maximum rainfall were 1884, when 90.12 inches fell, and 1894, when 44.49 inches fell.

## LOCAL CLIMATOLOGY.

### APTOS.

[Data from records of Southern Pacific Railway Company.]

Aptos is situated in Santa Cruz County, on Monterey Bay, about 7 miles southeast of the city of Santa Cruz, in latitude  $36^{\circ} 58'$  north, longitude  $121^{\circ} 54'$  west; elevation 102 feet above sea level.

The mean annual temperature, based upon records covering sixteen years, is  $56^{\circ}$ , which is practically the same as that of San Francisco, and  $2.4^{\circ}$  lower than the annual mean at Santa Cruz. June, July, and August are the warmest months, with mean temperatures of  $62.5^{\circ}$ ,  $62.3^{\circ}$ , and  $61.4^{\circ}$ , respectively; September is also a warm month, with a mean of  $60.9^{\circ}$ . The coldest month is January, with a mean of  $48.5^{\circ}$ ; the means for February and December are nearly the same. The maximum seldom exceeds  $90^{\circ}$ , the highest recorded in recent years being  $91^{\circ}$ , in June, 1898. Minimum temperatures of  $26^{\circ}$  are recorded in January, 1898, December, 1900, and February, 1901.

The average annual precipitation during the past sixteen years is 25.63 inches, about 1 inch less than that of Santa Cruz. The greatest precipitation occurs in December and January, but heavy rains also fall in November, February, and March. The rainfall during June, July, August, and September is very light and infrequent. During the month of December, 1889, the rainfall was 18.29 inches, and the total of that year was 37.94 inches.

## AUBURN.

Auburn is the county seat of Placer County, a narrow county in the central eastern portion of California, extending from Lake Tahoe and the Nevada line westward to Sutter County and the southern portion of Nevada County, and is situated in latitude  $38^{\circ} 54'$  north, longitude  $121^{\circ} 50'$  west, a short distance southwest of the junction of the middle and north forks of the American River. The elevation is 1,360 feet, with the land sloping eastward to the American River, where the elevation of the channel is about 500 feet. The Sierra Nevada Mountains, running through the eastern portion of the county, reach an elevation of 7,000 feet. The foothills are excellent fruit-growing districts.

The general movement of the air is from the north, northwest, and northeast. The date of the last killing frost in the spring of 1899 was May 2, and the first in autumn, 1899, was October 15. The mean annual temperature, based upon records covering a period of twenty-nine years, is  $60.1^{\circ}$ . The coldest month is January, with a mean temperature of  $45.5^{\circ}$ , and the warmest is July, with a mean temperature of  $76.7^{\circ}$ . During the months of June, July, August, and September the mean temperature exceeds  $70^{\circ}$ .

The highest temperature recorded within a period of twenty-two years was  $110^{\circ}$ , which occurred during the months of July and August, 1898. The lowest temperature recorded was  $12^{\circ}$ , in January, 1888. Reliable frost data are not available.

The mean annual rainfall for twenty-nine years is 33.58 inches. Two-thirds of this rainfall occurs between December and April. Rain seldom falls during July or August. The rainfall has exceeded 40 inches during six years of the twenty-nine, and in 1884 exceeded 50 inches. There have been but two years in the past twenty-nine when the rainfall did not reach 20 inches, viz., 1877, when but 18.07 inches fell, and 1898, when 19.96 inches fell.

## BERKELEY.

By Dr. ARMIN O. LEUSCHNER, Director of Students' Observatory.

SYNOPSIS OF METEOROLOGICAL OBSERVATIONS AT BERKELEY FOR THE YEARS ENDING JUNE 30, 1898, JUNE 30, 1899, AND JUNE 30, 1900, IN COMPARISON WITH THE TEN-YEAR SYNOPSIS, JUNE 30, 1887, TO JUNE 30, 1897.

In 1898 a ten-year synopsis of the meteorological observations taken at the Students' Observatory from 1887, July 1, to 1897, June 30, was compiled by Mr. R. Tracy Crawford, under direction of Dr. Leuschner and published in the University Chronicle, Vol. I. The ten-year synopsis is now being supplemented by a synopsis of the meteorological observations at Berkeley for the years ending June 30, 1898, June 30, 1899, and June 30, 1900, compiled by Mr. Y. Kuno.

To facilitate comparison of the annual means, etc., for these three years with the ten-year synopsis the corresponding figures of the ten-year synopsis are printed in the last column.

## BOCA

[Data from records of Southern Pacific Railway Company.]

Boca is situated at the junction of the Truckee and Little Truckee rivers, in latitude 39° 25' north, longitude 120° 5' west, and has an elevation of 5,535 feet; within a short distance are elevations of from 7,000 to 8,000 feet. It is in Nevada County, on the eastern slope of the Sierra Nevada Mountains, and has essentially a mountain climate. The general movement of the air is from the north, although southwest winds blowing down the valley of the Truckee River are frequent. Killing frosts occur late in spring and early in autumn. The mean annual temperature, based upon records covering a period of thirty years, is 43.8°. The coldest month is January, with a mean temperature of 25.9° December and February are also very cold months. The warmest month is July, with a mean temperature of 62.7°. The minimum temperatures for the last four years are as follows: Zero January 9, 1897; 12° below zero December 30, 1898, 30° below zero February 6, 1899, and zero December 31, 1900. The mean annual precipitation for thirty-one years is 20.14 inches. The month of heaviest precipitation is January, with an average of 4.30 inches. The snowfall for the past four years is as follows: 1897, 193 inches; 1898, 86 inches; 1899, 224 inches; 1900, 158 inches.

## CHICO

Chico is situated about 5 miles east of the Sacramento River, in the northern central portion of the valley, latitude  $39^{\circ} 43'$ , longitude  $121^{\circ} 51'$ . The lower foothills of the Sierra Nevada Mountains lie close to the east. While the elevation of Chico itself is but 193 feet, 10 miles east the contours approximate 1,000 feet, and 20 miles east elevations of several thousand feet are reached. The Sierra Nevada Mountains are not quite as abrupt and lofty here as elsewhere in the range. The general drainage of the air is down the main axis of the valley, that is, from the northwest; but there must also be a considerable movement of air from the northeast and east, backward over the mountains, with the passage of certain high areas eastward.

The mean annual temperature, based upon records extending over a period of thirty years, is  $63.8^{\circ}$ . The coldest month is January, with a mean temperature of  $46.7^{\circ}$ , and the warmest is July,  $83.9^{\circ}$ .

The highest temperature recorded within this period of thirty years was  $117^{\circ}$ . Temperatures exceeding  $100^{\circ}$  are not infrequent during June, July, and August. The lowest temperature was  $18^{\circ}$ , or an absolute range of  $99^{\circ}$ . The lowest temperature recorded in April was  $36^{\circ}$ , and in May  $40^{\circ}$ . The first killing frost in autumn last year (1899) occurred on December 12 and the last killing frost in spring on March 30.

The mean annual rainfall for twenty-nine years is 22.44 inches. More than half of this amount falls in the three months of December, January, and February. July is practically a rainless month, as only thrice in twenty-nine years has rain fallen to an appreciable extent. The rainfall is well distributed for agricultural purposes. During twelve of the twenty-nine years the total annual rainfall has not equaled 20 inches, but only twice has the rainfall not exceeded 15 inches. The driest year was that of 1898, when but 12.31 inches fell. The year of greatest rainfall was 1892, when over 36 inches fell.

## CORONADO.

By Mr FORD A CARPENTER, Observer, Weather Bureau

Coronado is practically an island; only a long and a very narrow strip of land connects it with the mainland. San Diego Bay may be likened to an inverted J lying northwest and southeast. Coronado lies snugly within the curve of the J and has a southern exposure. It is therefore readily seen that the climate of Coronado is substantially that of San Diego. The differences are slight and have only been determined by comparison of the records of self-registering instruments

Regular meteorological observations have been made at Coronado since the erection of the Hotel del Coronado in February, 1888, but it has only been a little over a year since a set of recording instruments has been installed. The instruments now used comprise a Richards barograph located in the hotel lobby (elevation 30 feet above sea level), one Richards thermograph and other recording thermometers exposed in a standard instrument shelter on the northwest lawn, 75 feet away from any building, tree, etc., and 20 feet above sea level. The rain gage is located on the lawn near the instrument shelter. The photographic sunshine recorder is mounted on the east tower of the hotel. Such is the instrumental equipment of Coronado as installed by the San Diego office of the United States Weather Bureau.

The region in which Coronado is situated lies too far south to be affected very much by the areas of low pressure that enter the Pacific coast near Vancouver. Probably four-fifths of the northern storm areas of winter are too distant to cause any fluctuations of the barometer. This is also true of the summer storms of the southwest. Areas of high barometer are almost as persistent during the winter months as areas of low pressure during the summer. The highs are responsible for the relative warm, dry, and clear winter weather, and the lows for damp, cool, and cloudy summer months.

<sup>a</sup> Data from the San Diego Weather Bureau station, which is 2½ miles northeast of Coronado and 60 feet higher.

## GILROY.

[Data from records of Southern Pacific Railway Company.]

Gilroy is situated near the southern line of Santa Clara County, 30 miles southeast of San Jose, in latitude 36° 59' north, longitude 121° 33' west; elevation, 193 feet.

The mean annual temperature, based upon records covering twenty-seven years, is 58.4°. July and August are the warmest months, with mean temperatures of 68.8° and 67.9°, respectively, and the coldest month is January, with a mean of 46.5°. The highest monthly mean recorded is 77.3°, in July, 1875, and the lowest 39.9°, in December, 1874. Following are the maximum temperatures in the past five years: 103° in August, 1897; 107° in July, 1898; 99° in June, 1899; 106° in August, 1900, and 104° in August, 1901. The lowest temperatures recorded in recent years are 23° in December, 1897, and 20° in December, 1898.

The average annual precipitation, from 1874 to 1900, inclusive, is 19.55 inches. The rainy season extends from October to April, the greatest precipitation occurring in December and January, and frequent rains occur in May and September. The greatest monthly precipitation recorded is 12.33 inches, in December, 1880, and the greatest annual, 32.95 inches, in 1884.

## HOLLISTER.

[Data from records of Mr. J. N. Thompson and Southern Pacific Railway Company.]

Hollister is the county seat of San Benito County, and is situated near the terminus of the Tres Pinos line of the Southern Pacific Railroad, 95 miles southeast of San Francisco, about 20 miles east of Monterey Bay, in latitude  $36^{\circ} 51'$  north, longitude  $121^{\circ} 25'$  west; elevation, 284 feet above sea level.

The mean annual temperature, based upon records covering twenty-seven years, is  $58.9^{\circ}$ . The warmest month is July, with a mean temperature of  $67.2^{\circ}$ , and the coldest is January,  $48.8^{\circ}$ . The highest monthly mean recorded in the last ten years is  $76.7^{\circ}$ , in July, 1891, and the lowest  $42.8^{\circ}$ , in January, 1898. The highest temperature recorded in recent years is  $105^{\circ}$ , in August, 1900, and the lowest is  $19^{\circ}$ , January 1, 1901.

The average annual precipitation during the past twenty-seven years is 12.31 inches, which is 7.24 inches less than the average for the same period at Gilroy, 15 miles to the northwest. The heaviest rains occur in January and December, and the greatest monthly precipitation in recent years was 7.35 inches, in December, 1889. Very little rain falls during the months of June, July, and August.

## LIVERMORE

[Data from records of Southern Pacific Railway Company ]

Livermore is located in the foothills of Alameda County, about 40 miles southeast of Oakland, in latitude  $37^{\circ} 40'$  north, longitude  $121^{\circ} 45'$  west; elevation, 485 feet

The mean annual temperature, based upon records covering thirty years, is  $59.7^{\circ}$ . July and August are the warmest months, with mean temperatures of  $70.1^{\circ}$  and  $69.6^{\circ}$ , respectively, and January is the coolest, with a mean of  $49.3^{\circ}$ . Maximum temperatures of  $103^{\circ}$  have been recorded in August, 1898, July, 1899, and June, 1901. The lowest temperature recorded in recent years is  $23^{\circ}$ , December 31, 1900. Minimum temperatures below  $32^{\circ}$  occur frequently in the months of January, February, and December, and occasionally in March.

The average annual precipitation from 1871 to 1900, inclusive, is 15.30 inches—about the same as that of Stockton. The greatest annual rainfall, 27.65 inches, occurred in 1884, and the least, 7.94 inches, in 1877. Rain seldom falls in July and August.

## MAMMOTH TANK.

[Data from records of Southern Pacific Railway Company.]

Mammoth Tank is situated in the eastern portion of San Diego County, on the line of the Southern Pacific Railroad, and in the southern portion of the Colorado desert, in latitude  $33^{\circ}07'$ , longitude  $115^{\circ}17'$ ; elevation above sea level, 257 feet.

The mean annual temperature, based upon records extending over a period of twenty-three years, is  $76^{\circ}$ . The warmest month is July, with a mean temperature of  $98.5^{\circ}$ , and the coldest January,  $53.9^{\circ}$ . The highest temperature recorded was  $130^{\circ}$ , on August 17, 1885, and the lowest  $22^{\circ}$ , in December, 1895, making an absolute range of  $108^{\circ}$ . Temperatures of  $100^{\circ}$  and over have been recorded in every month except January, February, November, and December, and temperatures of  $90^{\circ}$  and above in every month of the year. Temperatures of  $120^{\circ}$  and over have occurred in five months—May, June, July, August, and September. Temperatures of  $32^{\circ}$  and below have occurred in January, February, and December.

The mean annual rainfall for twenty-three years is 1.81 inches; the greatest annual, 5.48 inches, fell in 1889, and the least, a trace, in 1897 and 1898. The greatest monthly rainfall was 3.18 inches, in December, 1889. June has been practically a rainless month, no appreciable amount having been recorded during that month and only a trace once in twenty-three years.

## OAKLAND.

The thriving city of Oakland is located on the eastern shore of San Francisco Bay, in latitude  $37^{\circ} 48'$  north, longitude  $122^{\circ} 17'$  west, with elevations varying from 9 to 50 feet above sea level. It is the chief suburb of San Francisco, and has a population of about 75,000. The temperature and precipitation data following are from records kept by Messrs. J. B. McChesney, J. Hutchinson, J. B. Trembly, and Prof. Charles Burkhalter, of Chabot Observatory.

The mean annual temperature, based upon records covering twenty-five years, is  $56^{\circ}$ , practically the same as that of San Francisco. A comparison of the maximum and minimum temperatures of the two cities, however, shows that as a rule the days are warmer and the nights cooler

in Oakland than in San Francisco. July is the warmest month, with a mean of 61.8°, and January the coolest, 47.6°. The temperature seldom exceeds 90° and rarely falls below 32°.

The average annual precipitation is 24.96 inches, or nearly 2 inches more than that of San Francisco. January and December are the months of heaviest rainfall. Rain seldom falls during the summer months.

## REDLANDS.

Redlands is situated in latitude  $34^{\circ} 31'$  north, longitude  $117^{\circ} 11'$  west. The elevation above sea level, 1,352 feet. The city is surrounded by mountains and nestles on the southern slope of the San Bernardino Valley. Within a distance of 15 miles are a number of towns and small cities of which may be mentioned San Bernardino, Colton, Riverside, Loma Linda, Highland, and Craftonville. Mount San Bernardino and Mount San Gorgonio, two of the highest peaks in southern California, wall in the valley to the north. The distance from Los Angeles by rail is 66 miles. The city is generally conceded to be one of the most beautiful in southern California. The mean annual temperature is  $64^{\circ}$ , which is about  $2^{\circ}$  warmer than Los Angeles. The prevailing wind direction is west. Owing to proximity of the mountains and the desert, the range of temperature is large. Maximum temperatures exceeding  $105^{\circ}$  are not infrequent during summer afternoons, but it must be remembered that the relative humidity is very low. The highest temperature recorded since 1897 is  $113^{\circ}$  on July 11, 1897. The lowest temperature for the same period,  $26^{\circ}$  on January 1, 1901. Owing to the topography, however, lower temperatures may have been experienced within short distances from the point of observation. The annual rainfall, as determined from twelve years' record, is 14.70 inches.

## RIVERSIDE.

Riverside is situated in latitude  $33^{\circ} 58' 30''$  north, longitude  $117^{\circ} 22' 30''$  west. The elevation above sea level, 851 feet. The city lies in the valley of the Santa Ana River and is surrounded by hills and mountains. Riverside is said to be the largest orange-growing community in the United States. The city is a large one in area, approximating 56 square miles. About 35 square miles are under irrigation. The mean annual temperature is  $63^{\circ}$ , and the mean annual rainfall 10 inches. Afternoon temperatures in summer are high, often exceeding  $105^{\circ}$ . The highest recorded temperature since 1897 was  $112^{\circ}$  on September 11, 1898. The lowest temperature,  $26^{\circ}$ , has occurred on several dates.

## SALINAS

The Salinas Valley stretches in a southeasterly direction from Monterey Bay for a distance of 75 miles or more, having an average width of 10 miles. On the west side of the valley rises the Santa Lucia Range, with an altitude of about 5,000 feet, while on the east rises the Gabilan Range, of somewhat less elevation.

The city of Salinas has a mean annual temperature of 56°, based upon records extending over a period of twenty-six years. The coldest month is January, with a mean temperature of 48°, and the warmest July, 63°. The highest temperature recorded is 96°, and the lowest 20°, giving an absolute range of 76°. The date of the first killing frost reported during the past winter was December 6. Killing frosts in the spring may occur as late as the beginning of April.

The mean annual rainfall is 14.12 inches. This amount has been exceeded 13 times in the past twenty-six years. The rainfall is fairly well distributed for agricultural purposes. July and August are practically rainless. Twice in the past quarter of a century the annual rainfall has not amounted to 7 inches, viz, in 1898, when but 6.94 inches fell, and 1877, when but 6.81 inches fell. Both of these were unusually dry years in California. In June, 1884, 2.66 inches of rain fell. The two months of greatest rainfall were February, 1878, when 8.77 inches fell, and December, 1889, when 8.72 inches fell. No rain fell during the months of December, 1874, and February, 1896. During December, 1876, only a trace of rain fell.

The prevailing wind direction is from the south. In the summer months west and north-west winds are most prevalent, but from November to March south winds prevail. The largest number of rainy days occurs with south winds. During the past three years the average number of rainy days, i. e., days on which 0.01 inch or more of rain fell, were January, 7; February, 4; March, 5; April, 2; May, 1; June, 1; July, none; August, none; September, 1; October, 6; November, 4; December, 4. The number of clear days in January averages 16; in May, 11; in June, 20; in October, 16.

## SALTON.

[Data from records of Southern Pacific Railway Company.]

Salton is situated in the Colorado Desert, near the southern line of Riverside County, on the borders of Salton or Old Dry Lake, about 100 miles northwest of Yuma, and is 263 feet below sea level. The highest temperature in the past four years was 126°, July 13, 1900, and the lowest 20°, December 16, 1897. The total rainfall in the last twelve years was only 30.77 inches, an average of 2.56 inches annually.

## SAN BERNARDINO

By Dr A. K. JOHNSON, Voluntary Observer

Quoting from Professor Davis, of Harvard College: "The average value of the atmospheric conditions of a region constitutes its climate. The most important climatic elements are, first, temperature; second, various forms of moisture, as vapor, cloudiness, and precipitation; then, wind in cyclonic storms. The pressure of the atmosphere is not a climatic element and needs not to be considered only with the division of the wind system."

Taking up the study of San Bernardino climate under this division, the following tables will show the average temperature by months for the past nine years, together with the highest and lowest record and years in which it occurred.

## MEAN MONTHLY AND ANNUAL TEMPERATURE (DEGREES FAHRENHEIT)

Year	Jan.	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Annual

July . . . . .	1898	107	<sup>c</sup> 1891	47	Annual . . . . .		110		23

<sup>a</sup> Also in 1898<sup>b</sup> Also in 1896<sup>c</sup> Also in 1893, 1895, 1899<sup>d</sup> The cause of high temperature was an approaching thunderstorm, a very unusual occurrence<sup>e</sup> Also in 1894<sup>f</sup> Also in 1895, 1897

The daily variations are considerable, averaging 20°, sometimes running as high as 50°. This makes the nights always cool and pleasant, and the greatest variations are in the summer months. While the temperature is pretty high during the middle of the day, yet the dryness of

the atmosphere causes evaporation from the body, so the heat is not oppressive and sunstroke is unknown. Although it is more comfortable in the shade, yet the workmen are not bothered by the heat, as the writer observed some painters at work painting a tin roof without any serious inconvenience with the thermometer standing at  $107^{\circ}$  in the shade.

The temperature should be compared with the humidity table, which will show how dry the atmosphere is during the hottest part of the day.

The relative humidity was observed for three years, 1892, 1893, 1894. The following table will show the monthly average (per cent) at observations taken at 8 a. m., 12 m., and 8 p. m.:

Month.	Time of observation.			Mean.	Month.	Time of observation.			Mean.
	8 a. m.	12 m.	8 p. m.			8 a. m.	12 m.	8 p. m.	
January .....	69.6	45.3	67.5	60.8	August .....	78.2	44.5	65.6	61.1
February .....	77.9	54.6	77.7	70.1	September .....	71.6	41.5	68.2	60.4
March .....	76.5	58.8	79.2	71.5	October .....	73.8	48.3	74.4	65.3
April .....	71.8	45.8	74.9	64.1	November .....	68.7	42.0	69.0	59.9
May .....	77.1	53.0	76.6	68.9	December .....	77.2	56.3	72.7	68.9
June .....	71.8	45.1	68.5	61.8	Annual .....	72.9	47.8	71.4	64.0
July .....	65.8	38.7	62.2	55.5					

It will be seen that the mean at 8 a. m. averages 72.9 per cent and 71.4 per cent at 8 p. m., while at noon it averages 47.8 per cent. This explains why invalids should not be out of the house before 8 or 9 a. m. and be in the house before 8 p. m.

The rainfall each year is mostly during the winter months, although there are eight months that average over half an inch, the heaviest fall being in January. Instead of naming the seasons winter and summer, they are called the wet and dry seasons, but the season's rainfall is dated from July 1 and continues until the next June 30.

June . . . . .	24	6	0	1	Annual . . . . .	235	95	35	36
July . . . . .	23	7	1	1					

The prevailing direction of the wind is from the west and southwest in summer time; it drifts in from the ocean 60 miles away, greatly modifying the temperature. After the sun goes down a gentle breeze comes down from the mountains from the north and east, so that the air is hardly ever stagnant.

During the fall and winter north winds are frequent, but are regarded as beneficial in purifying the atmosphere, the same as thunderstorms in the East.

#### SANTA CRUZ

[Data from records of Mr RALPH SPRINGER and the Southern Pacific Railway Company ]

Santa Cruz, the county seat of Santa Cruz County, is an important city on Monterey Bay, about 80 miles south of San Francisco, in latitude  $37^{\circ}$  north, longitude  $122^{\circ} 02'$  west; elevation about 18 feet above sea level.

The mean annual temperature, based upon records covering twenty-eight years, is  $58.2^{\circ}$ , or about  $2^{\circ}$  higher than San Francisco. The warmest month is August, with a mean temperature above  $64^{\circ}$ , but June, July, and September all have temperatures exceeding  $63^{\circ}$ . The coolest month in the year is January, with a mean of  $51.1^{\circ}$ . It is apparent that the temperatures are very equable. The winter months are pleasant.

The average annual precipitation during the past twenty-three years is 26.97 inches, or nearly 4 inches more than the rainfall at San Francisco. December and January are the months of greatest rainfall, and more than half of the annual rainfall occurs during December, January, and February. The annual rainfall has varied from 13 inches to 44 inches. More than 20 inches of rain have fallen during eighteen of the twenty-three years.

## STOCKTON

The city of Stockton, latitude  $37^{\circ} 52'$ , longitude  $121^{\circ} 18'$  west, lies about 60 miles east of San Francisco. As the center of the great wheat belt of California, a record of the temperature and rainfall conditions is of the highest importance. Rainfall data covering a period of forty-nine years are available, but it is not known definitely to whom credit should be given for these records. On the books of the Weather Bureau are found the names of Dr. R. R. Reed, W. M. Trivett, M. Walthal, and T. G. Brown. Doubtless there are others to whom credit should be given.

## TRUCKEE

[Data from records of Southern Pacific Railway Company]

Truckee is situated in Nevada County, about 8 miles southwest of Boca, in latitude  $39^{\circ} 20'$  north, longitude  $120^{\circ} 11'$  west. Trout Creek joins the Truckee River at this point. Donner Lake lies about 2 miles west of Truckee, just north of the boundary line between Nevada and Placer counties. The elevation of Truckee is 5,818 feet, and of Donner Lake 6,095 feet. The general movement of the air is from the southwest down the Truckee Valley, but owing to the topography of the country there are many local air movements. Killing frosts occur frequently, as at Boca, and low temperatures prevail during the winter months. The mean annual temperature at Truckee, based upon records covering thirty years, is  $43.9^{\circ}$ , and is almost identical with that of Boca for the same period. Truckee is somewhat warmer in July than Boca, and a little colder in the winter months. The average annual precipitation, based upon records covering thirty-one years, is 26.60 inches. The month of heaviest precipitation is January, with an average of 5.61 inches. The snowfall for the past four years is as follows. 1897, 218 inches; 1898, 110 inches; 1899, 246 inches; 1900, 132 inches.

## MINIMUM WINTER TEMPERATURES OF THE HIGH SIERRA

(By Prof J N LE CONTE )

The following are the results of two observations on the minimum winter temperature of the summit of Mount Lyell in the Sierra Nevada Mountains of Central California. This point is situated about 18 miles in an air line and 40 miles by trail east of the Yosemite Valley. Its geographical coordinates, as given in the United States Geographical Surveys West of the One Hundredth Meridian, are. North latitude  $37^{\circ} 44' 11''$ , longitude  $119^{\circ} 16' 18' 07''$  west. Its elevation, according to the United States Geological Survey, is 13,041 feet above the sea.

Mount Lyell was selected principally on account of its comparative ease of access. The group of mountains of which it is one of the dominating points stands at the southern extremity of what may be called the "northern high Sierra," or that part of the crest of the great range lying between the headwaters of the Mokelumne River and those of the North Fork of the San Joaquin. In passing south along the high Sierra the summit peaks become progressively higher and more rugged, and the area above the timber line more extensive. About the head of the Merced River the northern portion culminates in a magnificent pile of snow capped peaks extending between Mounts Lyell and Ritter, where the southernmost glaciers of the range are to be found. South of Mount Ritter the crest breaks down in a wide belt of rolling, forest-covered mountains for nearly 20 miles, but rises again finally at Red Slate Peak. South of this the range extends as an unbroken wilderness of alpine peaks, rugged beyond description, culminating a second time in Mount Whitney, about 100 miles south of Lyell. This latter is the high Sierra par excellence.

On July 8, 1897, minimum thermometer No. 4315 of the United States Weather Bureau was left upon the summit. It was inclosed in a thin wooden box about 6 inches square and 2 feet long, one side of which was laid exactly in line with the edge of the great southern precipice, here over 1,500 feet high. Large stones were laid upon it, but one side was exposed to the weather, and in no way could it become entirely covered with snow. On June 5, 1898, the mountain was revisited, and the thermometer box was carefully uncovered. The thermometer was in perfect condition, and registered  $-13.6^{\circ}$  F.,  $-25^{\circ}$  C. It was reset and left upon the mountain a second year. Professor Le Conte was unable to make the ascent of the mountain in 1899, but Prof. H. I. Randall, of the civil engineering department of the State University, visited the spot in July and obtained the reading. In this case it was  $-17.6^{\circ}$  F.

It will be remembered that the winter of 1897-98 was an exceptionally dry one, and that of 1898-99 was not severe. It is interesting to compare these temperatures with those taken a few miles farther east and many thousand feet lower:

	1897-98.	1898-99.
Mount Lyell; elevation, 13,040 feet .....	-13.6	-17.6
Bodie; elevation, 8,248 feet .....	-24.0	-30.0
Bishop; elevation, 4,450 feet .....	+10.0	+ 5.0

It would be instructive to obtain the minimum winter temperatures of a number of high peaks distributed along the crest of the range from Lake Tahoe to Mount Whitney.

# SNOWFALL.

At the beginning of the year 1901 the weather bureau office at San Francisco made an effort to collect reports concerning the amount of snowfall in the mountains chiefly for the purpose of affording some data upon which forecasts of the probable supply of water available for irrigating, mining, and other purposes might be based. Not for many years had the snowfall been so heavy in central and southern California as during the winter of 1900-1901 and the outlook for an abundant supply of water so promising. It does not necessarily follow that a winter of heavy snowfall is succeeded by a season of bountiful water supply. In some States it has been found that dry ground absorbs so large a proportion of snowfall under certain favorable conditions that the anticipated run-off is not reached. Again, the melting of the snow may not occur rapidly enough and the evaporation prove excessive, especially if high north winds or mountain winds of the "Chinook" type prevail. Finally the manner in which the snow packs as it falls will determine largely the rate of flow during the ensuing warm months. During the month of February, 1901, the snowfall generally in the mountains of California was heavy. Particularly in the southern half of the Sierra Nevada and Sierra Madre was this the case. The following forecast was made at the close of February and was amply verified:

There is every prospect of an abundant supply of water during the coming spring and summer months. In the mountains of the central and southern portions of the State there is stored a sufficient quantity of well-packed snow, probably in excess of the amounts for any season for four or five years past. In northern California, while there will be an ample supply of water, the snowfall has not been as heavy as might have been expected during the wet winter.

Following are the notes made by different observers who were kind enough to make snowfall reports:

## JANUARY, 1901.

### NORTHERN CALIFORNIA.

*Bear Valley (near Emigrant Gap).*—Snowfall heavier than last year, but considerably less than average. The weather has been too warm for snow, but have had plenty of rain. Until four years ago the snowfall was from 8 to 14 feet on a level, but since then it has not been more than 4 feet. (James Rose.)

*Bodie.*—Snowfall last season, to January 26, 42 inches; this season, to same date, 139 inches. (Benjamin Robinson.)

*Edmonton (Meadow Valley).*—Average snowfall, 70 inches; this season, to January 26, 136 inches; last season, to same date, 47 inches; total precipitation this season, same date, 50.34 inches; last season, 51.35 inches. (J. A. Edman.)

*Greenville.*—Average snowfall, about 36 inches; this season, to January 3, 43 inches. The snow is melting slowly and will be of much benefit to crops. (C. H. Higbie.)

*Iowa Hill.*—The snowfall in 1890 was about 100 inches. It has been decreasing every season; last season, 8 inches. (C. F. Macy.)

*Laporte.*—Snowfall last January, 98 inches; this year, to January 26, 94.5 inches. The average snowfall from July 1 to June 31, for five seasons, is 288 inches. The average January snowfall is 76 inches. (C. W. Hendel.)

*North Bloomfield.*—The supply of water is probably not greater than last season, but depends upon February and March storms. Average snowfall, about 24 inches; above timber line, 84 inches. (L. L. Myers.)

*North San Juan.*—Average snowfall, 2 to 3 inches; at timber line, 6 to 8 feet; above timber line, 10 to 14 feet. (Dr. A. Fouch.)

*Quincy.*—Average snowfall, about 42 inches; will have best water season since 1897. (W. J. Edwards.)

*Red Bluff.*—More snow than usual; greater supply of water. (Maurice Connell.)

*Redding.*—Average snowfall, about 7 inches. In mountains to the west, snow very heavy and much above average; to the east (Sierras), much lighter. (L. F. Bassett.)

*Rosewood*—Average snowfall, about 8 inches; for 1899, 22 inches, 1900, none (C F. Stivers)

*Shasta*—Average snowfall, 8 inches, this year above average (Dr T J. Edgecomb.)

*Sisson*—From appearance of surrounding mountains there is double the amount of snow to same date last year. Mount Eddy and Mount Shasta are covered and canyons are full (C F Galbreath)

*Susanville*—Snowfall to January 31, 1894, 23 inches, 1895, 117 inches, 1896, 16 inches, 1897, 36 inches; 1898, 9 inches, 1899, 50 inches, 1900, 45 inches (James Branham)

*Truckee*—Average snowfall, 95 inches, at timber line, 13 feet, above timber line, 16 feet Snowfall for this season above average (C B. White)

*Yreka*—The snowfall this season, 63 inches, is greater than in any year since 1890 and the heaviest for one storm ever known (Robert Rankin)

## COAST AND BAY SECTIONS

*Eureka*.—In the mountains, at an altitude of 4,000 feet, the snow is deep It is reported that the snowfall is unusually heavy in Trinity and Siskiyou counties (A. H. Bell)

*Iaqua, Humboldt County*—Average snowfall; about 18 inches, this season above average. More precipitation this year than in any year since 1862 (W E Williams)

*Simmler, San Luis Obispo County*—No snow to date, average fall about 4 inches. Rainfall to January 26, 10 inches; total last season, 57.0 inches (A F Hubbard.)

## SAN JOAQUIN VALLEY

*Bigtrees, Calaveras County (elevation 4,700 feet)*—Snowfall, November 19 to January 10, 50 inches, rainfall to January 11, 29 inches. (J M Hutchings.)

*Bishop*.—Snowfall more than for several years, rainfall in Owens Valley greater than usual. (W A Chalfant.)

*Fort Tejon, Kern County*—Snowfall not above average, which is about 3 feet, and from 4 to 5 feet above timber line. (J G. Stitt.)

*Independence*.—Snowfall at station, 7 inches—about double that of last year and more than average for past four years The water supply will be very much greater than last season (John J McLean)

*Summerdale*—This season's snowfall (to January 31) is about 12 inches more than last season's, but less than average The average at timber line is 3 to 4 feet and above timber line 10 to 15 feet The rainfall has been the heaviest on record (J. H. Lowry)

*Tehachapi*.—Snowfall exceeds that of last season Average, about 3 feet, in the higher mountains, 12 feet. (W. H. Knapp.)

*Tejon Rancho, Kern County*—Creeks and springs are lower than I have known them for twenty years past (R M Pogson)

*Thebe, Inyo County*—Snowfall greater than last season's Average, about 12 inches, at timber line, probably 8 to 10 feet. (C Kispert)

*West Point*.—Snowfall about the same as last season's and considerably less than average. (T. A Wilson.)

## SOUTHERN CALIFORNIA.

*Beaumont*—Snowfall greater than last season's, but less than average, at timber line the average is 15 feet. (J. W. Elder.)

*Campo, San Diego County*—Snowfall exceeds last season's, but is less than average; the same is true of rainfall. (A. Campbell.)

*Cuyamaca*—Average snowfall for thirteen years, 33 inches, this season (to January 26), 1 inch. Owing to heavy rains, the water supply will probably be greater than last season (G H Nelson)

*North Ontario*.—Average snowfall in the mountains, 8 to 12 feet, the fall exceeds last season's, and the water supply will be greater (A. P. Harwood)

*San Jacinto*.—Snowfall in the upper valley on the 27th and 28th of January, from 6 to 10 inches (C A. Harper)

## FEBRUARY, 1901

## NORTHERN CALIFORNIA

*Bear Valley (near Emigrant Gap)*.—This season's snowfall is about 75 inches greater than last season's. Snow on ground February 9, over 5 feet, February 25, 30 inches, at the summit February 10, 14 feet Heavy warm rain reduced snow. (James Rose)

*Blue Canyon*—Very little snow left here now (February 23) The snowfall has been 4 feet greater than last season's. (J. Knapp)

*Bodie*—Snowfall greatly exceeds last season's, 48 inches on ground February 20. (Benjamin Robinson.)

*Bowman's dam*.—Snowfall much greater than last season's, 54 inches on ground February 28, 8 feet February 10, which was reduced by warm rains (A F. Hippert)

*Castle Crag*.—Snow on ground February 28, 10 inches, snowfall greatly exceeds last season's The water supply will be much greater than last season (H O Wickes.)

- Cedarville*.—Snowfall to February 25 has been 29 inches in excess of last season's; now on ground, about 12 inches. (T. H. Johnstone.)
- Dunsmuir*.—Snowfall greatly exceeds that of last season; on ground February 6, 60 inches. (R. K. Montgomery.)
- El Dorado*.—Snow on ground February 23, 4 inches; average fall at timber line, 12 feet; above timber line, 16 feet; snowfall greatly exceeds last season's. (C. E. Deuden.)
- Elder (Humboldt County)*.—Snowfall greater than last season's; on ground February 25, 6 inches. (William Lyons.)
- Eureka*.—On South Fork Mountains, 100 miles east, snow is reported 20 feet deep. Warm rains are melting snow rapidly. (A. H. Bell.)
- Georgetown*.—Snowfall exceeds last season's; 27 inches fell during February, but there is none on the ground now. (C. M. Fitzgerald.)
- Grass Valley*.—Snowfall exceeds last season's; none on ground at present. (B. F. Berriman.)
- Greenville*.—Eight inches of snow on ground March 1, and much heavier in timber; snowfall exceeds last season's. (C. H. Higbie.)
- Lyonsville (Tehama County)*.—This season's snowfall, 4 feet, has been the heaviest in three years, but there is none on ground at present. (J. C. Hillhouse, P. M.)
- Manton (Tehama County)*.—The snowfall is above average; on ground February 25, 12 inches. (W. E. Hazen.)
- Markleeville*.—The seasonal snowfall is more than double that of last season and the water supply will be much greater. (H. F. Musser, P. M.)
- Montague*.—The snowfall exceeds that of last season; on ground February 23, 42 inches. (H. A. Roterman.)
- Oleta*.—Snowfall this season, 4 inches, which melted the following day; last season, none. At elevations of 5,000 feet the snow has nearly all disappeared. (Isaac Cooper.)
- Placerville*.—More snow has fallen this winter than for many years, but there is none on ground at present. The average seasonal snowfall at timber line is 10 inches; this season, 4 feet. (J. Leigh Rowley.)
- Quincy*.—This season's snowfall, over 90 inches, is greater than last. On ground February 27, 12 inches. Average at timber line, 12 feet; above, 20 feet. (W. J. Edwards.)
- Rosewood*.—Snowfall last season, 1 inch; this season, 12½ inches; none on ground at present. At 4,000 feet elevation the average seasonal is about 3 feet; in January, this year, 6 feet. (H. F. Stivers.)
- Susanville*.—This is the best season since 1895; snowfall double that of last season. None on ground at present. (James Branham.)
- Truckee*.—Snowfall greater than last season's; on ground February 23, 9 inches; average seasonal at timber line 13 feet; above, 16 feet. (C. B. White.)
- Weaverville*.—Snowfall greater than last season's; none on ground here February 27; at timber line, about 3 feet; average at timber line, 8 feet; above, 10 feet. (A. S. Paulson.)

## CENTRAL AND SOUTHERN CALIFORNIA.

- Bishop*.—The season's snowfall exceeds that of last season and the water supply will be much greater. (W. A. Chalfant.)
- Independence*.—Greatest seasonal snowfall to date for nine years. At 11,000 feet elevation the approximate depth February 26, is 7 feet; average seasonal at timber line, 10 feet. (John J. McLean.)
- Mokelumne Hill*.—Season's snowfall greater than last; 6 inches fell during February. In the mountains the fall during February was greater than for several years. Creeks and springs are full. The water supply will be much greater than last season. (C. E. Prindle.)
- Summerdale*.—The season's snowfall to March 1 is 18 inches more than last season's; 28 inches now on ground. The snow is packed like ice and the ground is very wet. (J. H. Lowry.)
- Tehachapi*.—Seasonal snowfall greater than last; on ground February 24, 12 inches. Water supply will be greater than last season. (W. H. Knapp.)
- Campo*.—The snowfall exceeds last season's—in the valleys February 10, 6 feet; on the 26th, over a foot on the levels, with drifts 8 to 9 feet deep. Rainfall for season, 22 inches. (A. Campbell.)
- Cuyamaca*.—Snowfall to February 28, 49 inches, nearly all melted. Cuyamaca Lake is now at 24-foot level; last season it reached only the 13-foot level. (G. H. Nelson.)
- San Jacinto*.—More snow this season than for past four years; on ground near Strawberry Valley February 25, 42 inches. (C. A. Harper.)

Snow rarely falls along the coast of California; thus at San Francisco snow has fallen only on the dates following since March 1, 1871.

## DATES OF SNOWFALL IN SAN FRANCISCO SINCE MARCH 1, 1871

- January 21, 1876.*—Light snow fell for 10 minutes  
*December 31, 1882* —Heavy snow fell from 11 30 a m to 4 20 p. m ; amount, 3 5 inches  
*February 6, 1883* —A few flakes of snow fell during the day  
*February 7, 1884* —Snow fell at intervals during the day, depth varying from 1 to 2 inches  
*February 5, 1887* —Snow fell during the day; depth at office 3 7 inches, while in the western portion of the city it was fully 7 inches deep  
*January 4, 1888* —A few flakes of snow fell during the day.  
*January 16, 1888.*—Light snow fell to the depth of 0 1 inch  
*March 2, 1894* —A few flakes of snow fell during the day  
*March 2, 1896* —Snow mixed with rain fell at intervals during the day  
*March 3, 1896* —Heavy snow fell during the night, depth at office at 8 a m , 1 inch

Yet during nearly every winter snow may be seen upon the summit of Diablo, Mount Tamalpais, the Berkeley Hills, and ranges of Contra Costa County. Similarly in the southern part of the State during the months of January and February one may walk from the orange groves a comparatively short distance up the mountain sides and find snow. At Los Angeles, for example, in two or three hours one may pass from almost semitropical conditions into alpine conditions. Nearly every pronounced southeast storm during the winter months leaves a generous snowfall in the mountains of the entire State. The amount of snow varies naturally with the elevation, and also varies greatly with different storms. Heavy snow often falls on the ranges in the extreme southern portion of the State. In general the heaviest snowfall is found in the Sierra Nevada and the northern portion of the Coast Range. Elevations of from 3,500 to 5,500 feet apparently have a heavier snowfall than greater elevations.

Tables of snowfall in the Sierra for the last twenty-three years show that from 20 to 40 feet are not unusual annual snowfalls. At Summit there is a record of nearly 60 feet of snow during the year 1894. It is a matter of some difficulty to obtain reliable snowfall measurements. The ratio of 10 to 1, which is used by the Weather Bureau in reducing snow to rain, is but an approximation, and the ratio may be as large as 20 to 1 in the case of dry, fine snow at great elevation, and as small as 3 to 1 in the case of damp snow mixed with rain. A careful measurement at Fordyce, Cal., by Mr. E. E. Roeming, on February 8, 1901, showed a depth of snow as being 36 inches, but when melted it amounted to only 1 70 inches. It is plain that when the temperature is low it takes a large amount of snowfall to make an inch of water. In the case mentioned the ratio of snow to water was 21 to 1, and the writer has been told by reliable observers that in the mountains of California a ratio of 17 to 1 often prevails. On the other hand, at certain points a proper average ratio of snowfall to water would be about 6 to 1. In an article in the Monthly Weather Review for May, 1901, Mr. W. A. Bentley, of Nashville, Vt., who has made a study of snow crystals for over twenty years and has more than 800 photographs, no two alike, states that "the temperature and humidity of the air at the earth's surface is a much less important factor than is generally supposed in determining the form and size of the crystal."

Much has been learned, however, of the conditions tending to modify their forms after the nuclear form is once recognized. These conditions are chiefly the character of the cloud strata, the character of the storm and the initial and subsequent movement of the crystal within the cloud.

## NORTHERN SIERRA NEVADA.

By Mr. J. A. EDMAN, E. M.

The relation of snowfall to water supply can not be predicated upon the bare statement of precipitation and depth of snow alone, as so many other factors must be taken into consideration. To refer to the reports of observers to the Weather Bureau: What does an inch of snow stand for? It may mean all the way from one-ninth to one-fourth of an inch of water. Again, the absolute water contents of the settled snow depends not alone on its depth, but its relative compactness at the time of measurement, and may vary from one-seventh to one-third of an inch of water for one inch of snow.

The only conditions in the northern part of the Sierra Nevada under which a heavy snowfall insures a steady water supply are as follows: First, early rains beginning in October and gradual enough to soak into the surface without running off in sudden floods; second, abundant snows in December and January, with occasional rains, so that the snow may settle and become compact, and freezing of the surface soil prevented; third, occasional snowstorms during February and March, and an early but not too warm spring. Heavy precipitation and snowfall under other conditions do not insure an abundant water supply, as was well illustrated during the season 1889-90, when the precipitation at Edmanton reached 187.35 inches, and the depth of solid snow on the 15th of March attained 14 feet. Elaborate computations of the precipitation for that season in the Feather River basin, in connection with a record of flow at the Golden Gate mine near Oroville, showed that only 30 per cent of the water estimated passed off by the river during the spring and summer months. In this instance the spring of 1890 was marked by a very high temperature, and the first deep snows of 1889 fell on bare and frozen ground. The general water supply during that season was but little above the average. At this altitude (4,750 feet) and section of country it takes nearly 20 inches of water to fill the surface soil and start the deeper springs running, and even more after a very hot and dry summer.

The above-mentioned facts are well illustrated by the weather conditions during the seasons 1889-1900 and 1900-1901, as will appear from the subjoined tables:

1889-1900.			1900-1901.		
	Total precipi- tation.	Snow.		Total precipi- tation.	Snow.
October .....	15.88	19.0	August and September .....	0.25	0
November .....	13.09	6.0	October .....	12.51	0
December .....	11.89	22.0	November .....	13.13	20.0
January .....	10.99	0	December .....	7.70	22.0
			January (to 26th) .....	16.75	94.0
	51.85	47.0		50.84	136.0

An inspection of the above table will show the precipitation about equal for the two seasons, but the snowfall of January, 1901, far in excess of that of the corresponding month of 1900. The table, however, does not show that the conditions precedent during this season were specially favorable in contrast with the previous season, as the storms of October, 1899, were concentrated in a few days and the water passed off rapidly in injurious floods, while the rainfall of October, 1900, was well distributed over the whole month and largely seeped into the ground. The rains of December, 1899, fell on frozen ground and largely ran off, while in December, 1900, the thoroughly saturated ground received a cover of snow, to be reenforced in January, 1901, by heavy snows, now (January 26) averaging 4 feet in depth at this station, which acted upon by the warm surface soil feeds the streams independent of the general temperature conditions. Given a fair supply of snow during February and March it is reasonable to predict a good water supply during the summer of 1901.

## AT EDMANTON STATION

By Mr J A EDMAN, Voluntary Observer

The months of February and March, 1901, present a marked contrast to each other in regard to precipitation and also in snowfall, the record being as follows:

	Precipitation (inches)	
	February	March
Water, measured from rain . . . . .	9 47	0 68
Water, measured from snow . . . . .	5 89	4 26
Total . . . . .	15 36	4 94

The preponderance of rain during February is notable, as the mean temperature for the month was  $35.2^{\circ}$ , as compared with  $40.1^{\circ}$  for March. The rains of February having been almost continuous for eight days, and accompanied by strong winds and a mean temperature during the storm period of  $40.3^{\circ}$ , induced a rapid melting of the snow, and as a result the depth of snow (70 inches) at the beginning of the rainstorm was, at its close, reduced to an average of 40 inches. This reduction in the volume of the snow I have estimated as equivalent to 7 inches of water, making a run-off during a little more than ten days of 16.47 inches of water, and causing proportionate floods in the mountain streams.

The precipitation during March was much below the normal, and being mainly in snow, added 10 inches to the depth up to the 15th, which, although reenforced by a light snowstorm on the 27th, was reduced during the prevailing clear and comparatively mild weather of the latter half of the month to an average of 30 inches by the 1st of April. This depth of snow is roughly estimated, as great variation occurs according to exposure to sun and wind, many southern slopes now presenting large bare spaces, while drifts 5 feet deep may be seen on northern declivities and in sheltered spots in the canyons.

Ever since the high water of February the streams in this section of the Sierra have furnished a constant and but slightly varying water supply, which is being utilized by the miners, and which is apt to continue, and even to increase, during April and May, dependent on the temperature. The precipitation for the season, up to date, at this station, is 70.68 inches

The depth of snow on April 1, within a radius of 6 miles from this station, may be estimated as follows: In the zone below 3,500 feet altitude, little or no snow is found. From 3,500 to 4,000 feet, but little is seen on southern exposures, but an average of 20 inches on northern slopes and in the hollows. From 4,000 to 5,000 feet, about one-half of southern exposures are bare, and the snow there remaining does not exceed 20 inches in depth, while the northern slopes average fully 35 inches in depth. From 5,000 to 6,000 feet, bare spots occur on wind-swept southern exposures to an extent of 25 per cent in area, while the average depth of the whole zone may be given at 50 inches. From 6,000 to 7,000 feet, a few bare spots occur on windy points, while over the whole zone the snow probably averages fully 70 inches in depth. Three inches of the old snow may be estimated equivalent to 1 inch of water. The rains of February extended above the 7,000 feet zone in this region. The later snows have not reached below the 3,500 feet limit.

So far the outlook for a long-continued and regular water supply within the Feather River drainage area is very promising, providing normal temperatures prevail during April and May.

## CALAVERAS COUNTY.

By Mr. C. E. PRINDLE, Voluntary Observer.

The snowfall in the mountains of eastern and northern Calaveras County is several feet short of the average up to five and six years ago. The snows this winter have been light, and the rains have extended higher into the mountains than usual. The earth contains more springs and water at this date than it has for five years past. There is more water in the Calaveras River and all branches of the Mokelumne River (except the North Fork, which heads in Blue Lakes) than for several years past at this date, it being mostly rain water and not water from the snows. Dependence is not placed as much on the snowfall for a summer supply of water as in former years, for the reason that great forest fires have been so destructive to timber and undergrowth of late years that the snows do not remain on the ground long, but disappear from a month to six weeks earlier than formerly. Spring rains are more to be depended upon than snow for a summer supply of water.

Parties who have to-day returned from the higher range of mountains state that the snowfall is very light, in many localities there being none at all, where last year at this date there was 4 feet. Snow has fallen several times, but being followed by rain it did not remain long on the ground.

## LAPORTE.

The following record of snowfall at Laporte, Plumas County (elevation 5,000 feet), was made by Mr. Charles W. Hendel, voluntary observer. The record shows a yearly average of 299 inches. The snowfall for January, 1901, was 96.5 inches:

Year.	Jan.	Feb.	Mar.	Apr.	May.	Oct.	Nov.	Dec.	Total.	Year.	Jan.	Feb.	Mar.	Apr.	May.	Oct.	Nov.	Dec.	Total
1895.....	176.0	17.5	43.0	24.0	19.0	0.0	28.0	43.0	850.5	1899.....	114.1	26.9	117.8	25.3	12.7	27.3	22.0	52.9	899.0
1896.....	57.0	8.0	73.0	141.0	25.5	23.0	12.0	31.0	370.5	1900.....	18.0	22.9	52.9	28.9	1.0	6.5	37.1	28.2	195.5
1897.....	45.0	90.0	111.0	18.0	0.0	19.5	8.0	16.0	305.5	Average.	72.6	37.8	69.0	41.4	10.3	15.4	20.1	30.8	299.0
1898.....	25.5	61.5	16.0	11.5	3.5	16.4	15.5	13.5	172.9										

<sup>a</sup>Includes 7 inches in June and 2.5 in September.

## CUYAMACA, 1888-1900.

By Mr. G. H. NELSON, Voluntary Observer.

Year.	Jan.	Feb.	Mar.	Apr.	May.	Oct.	Nov.	Dec.	Total.	Year.	Jan.	Feb.	Mar.	Apr.	May.	Oct.	Nov.	Dec.	Total

## FROST.<sup>a</sup>

With the possible exception of the loss occasioned by insect pests, there is probably no one cause of loss so seriously affecting crops in California as frost. Notwithstanding statements sometimes published that certain areas are in the so-called frostless belt, there does not appear good reason for believing that any portion of the State may not be visited by frost.

The losses to the fruit crop, both citrus and deciduous, through frost have been so large that special attention has been given to methods of protecting orchards, and these methods are discussed in detail in the following pages. With citrus fruits the frosts of December, January, and February are to be guarded against, the fruit being ripe and ready for shipment. With deciduous fruits the late spring frosts do the damage. Almonds, apricots, grapes, peaches, and prunes are hurt while in bud, or while the fruit is just setting, by the frosts of March and April. The damage depends, in all probability, as much upon the condition of the tree as the degree and duration of the cold. For example, a sharp frost during the first or second week of April sometimes does less damage if the trees are fairly past the blossoming period than the same frosts would have caused occurring about the middle of March.

Attention is invited to the excellent table prepared by Mr. Samuel H. Gerrish, of Sacramento, giving the dates of first and last light and killing frosts, also the dates of blooming fruit trees in Sacramento from 1869 to 1901.

The protection of gardens, both vegetable and flower, is also important. The particular frosts affecting gardens are the frosts of February, March, and April, and it is pointed out in the succeeding pages that the same general principles used to protect orchards should be followed in the protection of gardens. A clear, still night following thirty-six or forty-eight hours of boisterous north wind is likely to be followed by frost, particularly if the movement of the air in the given locality has been such as to cause a settling of cold, relatively dry air strata in the hollows or depressions of the land. The formation of frost is essentially a problem in air drainage, and if by any means we can prevent streaks, pools, or basins of stagnant, cold, dry air we can largely prevent frost. Frost is the water vapor of the air deposited upon the plant at a temperature below 32° F. The damage to plant life is caused by the falling temperature. The water vapor plays the part of an index only. Indeed, the action of the water vapor is preventive. Dry air at a temperature of 32° F. weighs 563 grains per cubic foot. Vapor of water at 32° F. weighs 2.1 grains per cubic foot at a saturation of 100 per cent. Air at a temperature of 25° F. weighs 572 grains per cubic foot. Given a little time, therefore, on a still, clear night the loss of heat by radiation from the plant surfaces and the ground will bring about a settling of the colder air to the bottom. The ground will be covered with frost, while thermometers 6 feet above the ground will record 34° or 35° F. Vegetables and flowers, therefore, unless grown upon sloping or terraced ground, are at a decided disadvantage compared with tree fruit in the matter of frosts.

### NATURE OF FROST.

It can not be emphasized too clearly that it is the low temperature and not the solidification of the water which does the damage. If there be but little vapor in the air there will be but a light frost apparent, and yet the temperature may be so low as to cause great injury. The so-called hard, dry frost, also called black frost, does, as is well known, even more injury than

<sup>a</sup>Since this article was written a number of orchard-heating devices have been patented by various frost prevention companies in California. Oil fire pots have been tested and it is claimed given very satisfactory results. Gravity oil distillate is used as fuel and about eighty oil pots to the acre will insure protection.

heavy frosts. Water vapor at 25° F. completely saturated weighs 1.6 grains per cubic foot. In the fall from 32° to 25° nearly half a grain per cubic foot, if the saturation were 100 per cent, would be condensed, appearing in visible form as a frost flake. A certain amount of heat was given off in the transformation of this invisible water vapor into ice, and an exactly equal amount of heat (known as the latent heat of vaporization) will be in turn required to change this frost flake back into vapor. We give special attention to this point because it would appear theoretically that the secret of successful protection of garden truck and delicate flowers will be found in this action of water, both in setting free heat at the time when the temperature is falling, and on the other hand in using up heat and thus acting as a retard or brake when the temperature begins to rise quickly.

It is now quite generally believed that as much injury results from the sudden warming up of the dormant and thoroughly chilled flower or vegetable as from the chilling itself. In the work of protecting fruits from frost it has been found very necessary to interpose some screen early in the morning between the sun's rays and the frosted fruit. With flowers and garden truck this can be much more easily accomplished than with fruit. In this respect the gardener has a decided advantage over the orchardist. The following is an excellent statement of how the plant is injured:

#### HOW FROST INJURES PLANTS

Low temperature congeals the watery part of the cell sap and also the intercellular water content of the plant. Within certain limits this is not or may not be injurious, providing the protoplasmic contents of the cell are able to absorb the water and do this before the cell structure collapses as a result of insufficient cell turgor. Frequently the frosting of plants is followed by a sudden rising of temperature, in which case much of the water which was part of the cell sap in the normal condition of the plant escapes through the cell wall into intercellular spaces, or even from the plant entirely, and thus, the protoplasm of the cell being unable to assume its normal condition, becomes disorganized and decomposition follows (Prof E R Lake in the Oregon climate and crop bulletin, July, 1900 )

#### PROTECTION OF ORCHARDS FROM FROST.

During the past five years the Weather Bureau office at San Francisco has been called upon to give particular attention to the problem of lessening the injury to fruits by frost. By direction of the Chief of the Weather Bureau, during the year 1900 the forecast official for the southern half of the Pacific slope made an extensive journey through California with the special purpose of studying the methods of protecting deciduous fruits from frost. This journey was the natural outgrowth of the excellent work inaugurated by Mr. W. H. Hammon, formerly professor in the Weather Bureau, while in charge of the San Francisco office. During the years 1897, 1898, and 1899 the unusually dry winter conditions, with frequent and prolonged frosts and lower temperatures than had been previously reported in many of the chief fruit-growing centers of southern California, made it imperative that some steps should be taken to minimize the injury to citrus fruits by frost. The problem as presented to the forecast official was of a twofold nature. First, a study of the conditions preceding frost, so that he might with reasonable certainty give timely warning to the fruit growers; second, a study of the methods, means, and devices for protecting fruit from injury by low temperatures. The first has been solved with a fair measure of success. In the second problem the Weather Bureau had the valuable assistance of certain practical fruit growers, who willingly and readily tested the various devices proposed for smudging and cheerfully gave this office the benefit of the many practical experiments made by them in smudging, irrigating, heating, and covering. A bulletin on frost fighting, by Alexander G. McAdie (Bulletin No. 29), was issued on March 13, 1900, and nearly 3,000 copies distributed to those most interested in fruit growing. A previous bulletin (No. 23) upon frost, when to expect it and how to lessen the injury therefrom, by Prof. W. H. Hammon, had been issued on November 10, 1898, while a Farmers' Bulletin, No. 104, by Prof. E. B. Garriott, Notes on Frost, was issued June 15, 1899, which treated of frost protection in general.

It has become evident in California that the fruit grower must possess a degree of intelligence certainly as high as is demanded in any one of the usual vocations of life. The successful

orchardist must be a skilled farmer and a good business man and, at the same time, be familiar with the chief principles of modern science. He must be chemist, entomologist, and physicist, as well as fruit grower. In the matter of protecting his crops from frost, for example, he must know exactly what method is best suited for his crop, for the locality, and for the season, and be prepared to act promptly, or else the greater portion of the year's profits will vanish in the course of a few hours.

In what follows extensive use will be made of Bulletin No. 29, since experience has shown that the principles of frost fighting laid down therein are essentially correct. While this bulletin was written chiefly with a view of protecting the citrus fruit crops of California, particularly of the section south of the Tehachapi, from frost, the principles hold, as a general rule, for the protection of deciduous fruits also.

In October and November, 1900, an attempt was made to extend the benefits of the Weather Bureau work in connection with frost to the fruit growers of central and northern California, particularly to the growers of almonds, apricots, peaches, prunes, pears, apples, grapes, and figs. Many fruit ranches were visited, and the details of losses by frost gathered from ranch superintendents and others, together with all data available relative to the exposure of the fruit, the lay of the land, and the lowest temperatures. The following facts stand out prominently from the general mass of statements. First, that in California the greatest injury is done deciduous fruits by the late spring frosts occurring as late as the 23d of May, when fruit is well formed, frequently resulting in the loss of three-fourths of the crop in the case of the more tender fruits, as for example, almonds and apricots. Second, in all the fruit ranches visited rough maps of the localities showed conclusively that the frost occurred chiefly in the low places, basins, and bottoms, or where the cold air had drained down and settled. The principle laid down in Bulletin No. 29, that frost was primarily a problem in air drainage, was conclusively upheld. Wherever the air was stagnant the injury from frost was most marked; and, conversely, wherever the air was in motion there was little damage from frost. Fruit on open benches, hillsides, and terraces escaped. The streakiness of frost and the many apparent irregularities in its formation can be explained easily if we remember that there are currents and stream lines in the air, and that these currents may have rather sharply defined limits. A slow-moving current of air on a still night in an orchard that appears to be nearly level may result in an absence of frost along its path, while close by, where the air is stagnant, frost will be formed.

A third particular point resulting from this visit to the ranches was the confirmation of the belief that the damage from frost could be greatly lessened if some means were provided whereby the chilled fruit could be protected from the sudden warming at sunrise. Some rough temperature observations made in ranches at about the time of sunrise on frosty mornings showed a rise of as much as  $10^{\circ}$  in the air temperature within thirty minutes. It was also noted in several ranches that the areas of greatest loss by frost were those where the sun's heat came suddenly upon the trees. It is believed that much fruit can be saved even when chilled or frozen if some screen is interposed between the fruit and the sun, so that the warming may be gradual. It is even admissible to thoroughly wet the fruit with cold water, and there are numerous instances of fruit escaping serious injury even when it has been covered with a thin coating of ice. It is of the utmost importance that the thaw for an hour or two following sunrise be gradual.

The following methods of protecting fruit from frost are taken from Bulletin No. 29:

#### METHODS OF PROTECTING.

Every fruit grower should put himself in communication with the nearest center of distribution of weather forecasts. If possible he should be in daily communication with some Weather Bureau office. Whenever frost warnings are issued for his locality he should carefully determine the temperature and dew-point, as elsewhere described, frequently during the late afternoon and night. A good outfit consists of a metallic thermometer so arranged as to automatically close an electric circuit and ring an alarm whenever the temperature of the air reaches  $32^{\circ}$ . In addition to a reliable sling psychrometer there should be some small device for testing the motion of the gentle air currents in the orchard. Too much attention can not be given to this question of air motion. Many smudging devices have failed to be effective because of a slow movement of the smoke away from the orchard.

## PROTECTIVE METHODS BASED ON MIXING THE AIR

It is well known that lowlands are visited with frost while hillsides and hilltops escape. Every fruit grower should study the topography of his land and plant accordingly. Wind-breaks are, as a rule, considered detrimental. No hard and fast rule, however, can be laid down. On a well-known lemon and orange ranch at Santa Paula, the

FIG. 13.—Wire baskets in citrus grove

property of Mr. N. W. Blanchard, there are several large wind-breaks which have proven themselves to be of the greatest benefit in protecting fruit from frost. It would almost seem as if the citrus trees within a distance of 50 feet were directly protected by these wind-breaks. By planting a wind-break in the proper place, defects in the

FIG. 14 —Wire baskets hung from limbs of orange trees

topography may be overcome and air currents established where otherwise pools of quiet air would have formed. A wind-break dense enough and so situated as to interfere with any natural circulation and facilitating the formation of still areas or pools would, of course, prove injurious.

## PROTECTIVE METHODS BASED ON WARMING THE AIR.

A large number of small fires, advantageously placed, will raise the temperature of the air several degrees. The Riverside Horticultural Club, testing the various methods which were in use in California, came to the conclusion that wire baskets suspended a few feet above the ground, and holding several pounds of coal or charcoal, made an efficient protector. This method was described by Mr. Edward Copely, of Riverside, Cal., in several articles published in the Riverside Press of April, 1896. The cost of the wire basket is about 10 cents, and if 40 baskets be used to the acre, the cost of fuel will hardly exceed \$2.50. To this must be added the cost of labor during the night and succeeding day in refilling the baskets. In the accompanying figs. 13, 14, and 15, the baskets are shown in position. This method meets with most favor in southern California. The temperature can be raised certainly 3° or 4° with from 20 to 40 of these baskets to the acre. It has been suggested that a number of small oil lamps be used with success for this purpose. Oil pots have been used and make a hotter fire, but the deposit of lamp black upon the fruit is objectionable. Some cheap modification of the ordinary plumber's furnace might possibly be devised, which, by means of a moderate blast, would produce a high temperature.

## PROTECTIVE METHODS BASED ON CLOUD OR FOG FORMATION.

Damp straw, old wood, prunings, manure, etc., when burned briskly furnish an effective smoke, and if the material while burning is doused with water the result is a dense steamy smoke, which, while trying to human lungs, serves as a screen to prevent loss of heat by radiation, and as a barrier between the chilled fruit and a sudden

FIG. 15.—Wire baskets in lemon and orange grove.

application of heat at the time of sunrise. Wet smudging has been tried in many ways with varying results. There are many reports of failure and, on the other hand, some definite results, showing the good accomplished by this method. Here, as in all other methods of protection, much will depend upon a careful study of the local conditions. Many a farmer smudges so that some neighbor gets the benefit of his work, while his own fruit remains unprotected. All motion of the air should be noted carefully, and this is sometimes difficult where the smoke is very dense. In some orchards sacks of old straw soaked with oil are so distributed as to be available for quick lighting. Portable smudges have also been devised. Fig. 16 illustrates a portable device by Mr. Priestley Hall.

Mr. Hall has made an efficient form of sled operating on the wet-smudge principle. Upon a sheet-iron sled he has placed a small fire box, consisting of a grate 4 or 5 inches above the bed of the sled, over which pass iron rods bent in the form of an arch, leaving a space for the fire about 14 inches in diameter. This fire box is inclosed in a large corrugated iron box, which has the bed of the sled (about 3 or 4 feet in size) for a bottom, and sides 30 inches high. A door is made in front of the corrugated box to admit fuel to the fire. The box is filled with wet straw or manure, and a fire is maintained in the fire box when the machine is in operation. The cost is about \$12; one will do for 10 acres.

## PROTECTIVE METHODS BASED ON IRRIGATION.

Of all methods proposed for the protection of fruit, excepting wire baskets, irrigation has the largest amount of evidence in its favor. It has been tried in many different places with different crops and has generally given satisfaction. Where water is not very plentiful, and this is the case strangely enough in some fruit sections, the method

may not always be practicable, but with this exception there are many decided advantages in the generous use of water. Injury from frost depends almost as much upon the condition of the tree as upon the severity of the weather. Critical periods in the life of the tree can be controlled to some degree by the use of water.

Some fruit growers hold that heat is the one thing that is desired at times of frost, and that the best method is that which produces heat by the simplest and least expensive process. Water, owing to its high specific heat, forms

FIG. 16.—Mr Priestley Hall's device for smudging.

an excellent agency for the temporary storage of heat energy. We have seen that in the wet smudge an attempt is made to utilize the latent heat of vaporization, and theoretically this has always seemed the most advantageous method. A modification of the wet smudge is steam piped through an orchard. This experiment was made by the Wright Brothers at Riverside, Cal., with a 35-horsepower boiler and a main pipe 2 inches in diameter, from which,

FIG. 17.—Eight miner's inches of warm water in orange grove at Meacham Ranch

at right angles every 40 feet, pipes three-quarters of an inch in diameter were extended. It is claimed that the temperature was raised 3° whenever the steam was turned on. It is also said that the coal consumed would not be more than the amount used by the basket method. The estimated expense per acre would be about \$75.

The latest device for the protection of citrus fruit against frost combines the good effects of irrigation with heating. This is a method known as the warm-water method, tried at Riverside. An account of the experiment follows.

EXPERIMENT OF MR. ERNEST A. MEACHAM, RIVERSIDE, CAL.

"On the morning of February 9, 1900, at the Meacham Ranch, a test was made of the Meacham warm-water method of protecting citrus fruits against frost. The experiment began at 3.45 a. m. and was conducted in the presence of a number of gentlemen belonging to the Riverside Horticultural Club, nearly all of whom were orange growers.

"At 6.30 a. m. the temperature of the ground 100 feet or more away from the boiler was 32°. The temperatures given herewith are those obtained by Mr. McAdie, of the Weather Bureau, with sling psychrometer No. 70; the number of the dry thermometer was 4487 and of the wet 4486. The plant consists of a 12-horsepower tubular horizontal boiler, laid in a brick furnace and arranged to deliver water with or without pressure. Cold water enters the bottom of the boiler and is delivered from the top orifice directly into the flume. The fuel used was crude petroleum, of which about 50 gallons were used in three and one-half hours. At the rate of 14 gallons an hour and an estimated cost of a little over 4 cents per gallon, the actual expense of fuel for the experiment was about 60 cents per hour. The oil is burned with a steam jet under pressure. A secondary 6-horsepower boiler, carrying 70 pounds of steam, was used. The oil is thus entirely consumed and makes but little smoke. The whole arrangement is such that not more than two men would be required to attend to all the details.

"Fifty minutes from the time of beginning, the water which had an initial temperature of 55.4° was raised 30°. Two sets of temperature records were made, one by Mr. Priestley Hall and the other by Mr. McAdie. In Mr. Hall's test 8 inches of water was run in 50 furrows, which barely ran the water past the ends of the furrows. In the second case 8 miners' inches of water was delivered into 25 furrows, thus carrying the heat farther down the furrows than

FIG. 18.—Lath screen at ranch of Mr. A. J. Everest, Riverside, Cal. (view from above).

in the first experiment. According to the present laws of California, a miner's inch is  $\frac{1}{7}$  cubic foot per second; the 'second-foot' is the quantity represented by a stream 1 foot wide and 1 foot deep, flowing at the average rate of 1 foot per second. A cubic foot of water, maximum density, weighs 62.4 pounds; a gallon contains 10 pounds of distilled water at 62°. The data obtained by Mr. Hall were as follows: 5.30 a. m., normal temperature, 34°; normal temperature of water, 60°; temperature of heated water, 92°; at the flume, 92°; 20 rods from the flume, 58°; 40 rods, 52°; temperature of unheated water 40 rods from the flume, 41.5°; vapor condensed on trees early in the morning and more condensed on the trees in the heated plat.

"Mr. McAdie's records are as follows: Time, 6.30 a. m., air temperature varying from 34° to 36°; temperature on the ground, 32°; frost was observed on grass blades; initial temperature of water, 55.4°; heated water delivered to flume at 85.2°; in a straight line down a furrow 200 feet from the boiler in the direction of the wind (motion of the air was very gentle) there was a fall in temperature of 14.2°; water vapor was observed rising to a height of about 4 feet; 200 feet from flume, as stated, the temperature of the water was 71°; the temperature of the surface soil 4 inches right and left of the water was 43°; temperature of the soil 16 inches from the water or in the middle of the ridge, 42.2°. It is presumed that the temperature of the ground, had no water been flowing, would have been 33°, and it would seem as if the soil itself was warmer by nearly 10°. At the end of a furrow, 600 feet, the temperature of the water was 54°, or there had been a fall of 31° in 40 rods; the temperature of the ground 4 inches from the water, 38°; 16 inches from the water, 36°; temperature of unheated water 50 rods from the flume, 40°.

"The approximate value of the plant was \$200, and it is estimated that for a plant all equipped sufficient for a 10-acre grove \$600 would cover all expenses." (See fig. 17.)

## SPRAYING.

After frost, or rather just before a frost has ended, a spraying device can be used to advantage. Its chief function is to prevent a too rapid warming of the chilled fruit. It is said by horticulturists that even the light coating of ice formed in this way does not seriously damage the fruit. It is very likely that the latent heat of solidification set free by the change from water to ice may play a helpful part; but the chief effect is to prevent a too rapid thawing. In other words, both heat and water should be supplied to the chilled plant slowly and according to the plant's ability to make good use of the same. At the A. J. Everest Ranch at Riverside, Cal., a portion of the grove is protected by sprinklers at the top of 50-foot masts.

FIG. 19.—Lath screen at ranch of Mr. A. J. Everest, Riverside, Cal. (under view)

## PROTECTIVE METHODS BASED UPON SCREENING OR COVERING

All screening or covering devices are in effect modified hothouses, and there is no question but that a thorough protection can be accomplished. The expense is the one objection. Screens are made of light materials, namely, canvas, muslin, or light wood work, and have been used with considerable success. At the A. J. Everest Ranch an elaborate structure of lath screens is in use, illustrations of which are given herewith (see figs. 18 and 19). There is no question as to the value of the protection, but the expense is considerable, averaging perhaps \$400 to the acre. This lath covering may be considered as forming a well-ventilated hothouse.

## FROST.

235

## KILLING FROSTS.

The following table gives the dates on which occurred killing frosts during the year 1899—the last in spring and first in autumn—at stations recording and reporting frosts. The blank spaces in the table indicate that there were no killing frosts at those stations for the period shown, or, in some few cases, that the record is incomplete.

NOTE.—Killing frosts occurred in every month of the year at Bodie, Mono County. The observer at Los Angeles reports that there were no killing frosts at that station during the year; the first heavy frost occurred December 11, damaging vegetables in exposed places. At San Diego the most severe frost for five years occurred February 6, but did not damage orchards or fruit in citrus region.

## FOG.

---

One of the most marked atmospheric conditions with which the forecaster has to deal on the coast of California is fog. Particularly in the vicinity of San Francisco are the effects of the fog noticeable. Owing to the peculiar topography of this section, there are certain well-marked stream lines in the general movement of the air from west to east; and in these streams great masses of the condensed-water vapor lying beyond the heads and along the coast are carried in through the Golden Gate. There are times when, judging from such reports as are available, fog prevails along the entire Pacific coast. On the daily weather map which is issued at San Francisco attention has been called several times within the last few years to the fact that nearly every coast station reported fog, thus indicating the presence of a bank of fog at sea from 1,400 to 1,600 miles in length. The distance seaward to which this fog extended is not known, but from the records contained in logs of vessels sailing from San Francisco it is thought that an average value would be about 50 miles. Now, fog, whether it appears for a few hours at certain seasons, as in the harbors of the Atlantic coast, or regularly on summer afternoons and winter mornings along the Pacific coast, and whether it lies in sharply defined streams and strata, as at San Francisco, or in ill-defined general banks, as off Newfoundland, indicates certain sharp contrasts of temperature and air motion. On the Pacific coast there are several well-marked types of fog—the summer afternoon fog, moving from the sea to the land; the morning winter land or tule fogs, which move seaward, and occasional nondescript smoke fogs near the larger cities.

At Mount Tamalpais we are able to look down upon the fog streaming through the Golden Gate. On one side the ocean maintains a temperature of about  $55^{\circ}$  F., while inland the temperature is much higher. Some illustrations of the fog effects as photographed at the Weather Bureau Observatory were published in the Monthly Weather Review for July and November, 1900, and January, February, and March, 1901, and are here reproduced.

The differences in temperature, humidity, and air motion are so marked within comparatively small distances, both horizontally and vertically, in the bay district that it seemed advisable to tabulate in comparative form the meteorological elements for a year at the higher station (elevation approximately half a mile) and the station at sea level. The present paper aims to present, with some photographic evidence of fog forms and drifts, a rough study of the air drainage of the locality in which fog streams and counter streams are of such frequent occurrence that they serve excellently as exponents of air motion. The topography of the section is remarkable, because of the close juxtaposition of ocean, bay, mountain, and foothill. A valley, level as a table, 450 miles long and 50 miles wide, having afternoon temperatures of  $100^{\circ}$  or over, is connected by a narrow water passage with the Pacific Ocean, the mean temperature of the water in this locality being  $55^{\circ}$ . Thus within a distance of 50 miles in a horizontal direction there is frequently a difference of  $45^{\circ}$  in temperature, while in a vertical direction there is often a difference of  $30^{\circ}$  in an elevation of half a mile. High bluffs, ridges, and headlands are at such an angle to the prevailing strong westerly surface air currents that an air stream is forced with increased velocity through the Golden Gate, and there must of necessity be considerable piling up of both air and water vapor at this point. The locality may indeed be considered as a natural laboratory in which experiments connected with cloudy condensation of water vapor are daily wrought, and it is therefore of more than passing interest to the meteorologist.

Much faithful work has been done in physical laboratories on the behavior of water vapor at varying volumes, pressures, and temperatures. Regnault, Thomson, Broch, Aitken, Kiessling, R. von Helmholtz, Hertz, Rayleigh, Von Bezold, Barus, Marvin, and others have worked upon the change of state from vapor to liquid and from liquid to solid; and while many irregularities are noted in the behavior of water vapor, the general problems of decreasing volumes and increasing pressures until condensation points are reached have been solved, and it is well understood that the vapor-liquid and liquid-solid condensations are in themselves but two phases in a chain of condensation phenomena. The problem of fog is therefore a limited one. It may be considered as a special case of cloud development, occurring in the first and second stages of Hertz, viz, the unsaturated and saturated stages. Condensation in the free air, as in these fog formations, takes place under conditions different from those obtaining in the laboratory. There are no fixed, restraining walls, though the strongly stratified outlines suggest sharply limited air streams. Again, saturation as it occurs in free, constantly changing air and true adiabatic saturation are not identical. Saturation in the free air must be studied under disadvantageous circumstances, for the work must be done at a distance, with instruments neither sufficiently delicate nor accurate, and there is no control of conditions possible. In passing it may be noted that, except for traces of salt, the air of the section under consideration is partially filtered, as it presumably comes from off the broad ocean and is as free from land dust and smoke as normal air can be. Offshore winds are infrequent and light.

An attempt has been made at the Mount Tamalpais station to correlate the surface pressure conditions with fog. A typical pressure distribution accompanying sea fogs has been recognized. In general, a movement southward along the coast of an area of high pressure in summer means fresh northerly winds and high temperature in the interior of the State, with brisk westerly winds, laden with fog, on the coast.

An excellent illustration of a successful forecast of fog may be found in connection with the daily weather map of June 30, 1899, and also July 1, 1899. It should, however, be stated that fog does not always occur with these typical fog maps. For example, on June 28, 1899, the pressure distribution was such as to lead to the expectation of fog, but no fog was reported on this date.

#### COMPARATIVE DATA FOR SAN FRANCISCO AND MOUNT TAMALPAIS.

In Bulletin No. 28 issued by the Weather Bureau, entitled "The Climate of San Francisco," meteorological data pertaining to the city of San Francisco are given up to the beginning of 1899. It is not necessary to repeat here these records; but the data for 1899, being available, possess special interest:

Mean monthly temperatures.			Mean monthly temperatures.			Mean monthly temperatures.		
Year and month.			Year and month.			Year and month.		
	Mount Tamalpais.	San Francisco.		Mount Tamalpais.	San Francisco.		Mount Tamalpais.	San Francisco.
1899.	°F.	°F.	1899.	°F.	°F.	1899.	°F.	°F.
January .....	47.8	53.0	June .....	66.8	58.9	November .....	49.4	50.8
February .....	47.6	51.6	July .....	71.0	55.9	December .....	47.7	49.0
March .....	44.6	52.2	August .....	61.4	58.3	Annual .....	55.6	54.9
April .....	51.6	54.6	September .....	73.2	58.2			
May .....	51.2	52.6	October .....	55.3	59.3			

These temperatures, compared with those of 1898, show that the annual mean temperature of both stations for the two years is practically 55°, which is also the mean annual temperature, so far as we can judge from somewhat scattered data, of the ocean in the vicinity of San Francisco. The temperature of the lower station naturally approximates sea conditions throughout the year, while the departures at the more elevated station are marked in both winter and summer.

The highest temperature recorded on the mountain during the year was  $96^{\circ}$ , on July 18; the maximum temperature on the same date at San Francisco being  $66^{\circ}$ , and at Point Reyes  $52^{\circ}$ . It is worthy of note that within so short a distance as 25 miles, between Mount Tamalpais and Point Reyes, there should be a difference of  $44^{\circ}$ . The highest temperature recorded at San Francisco during 1899 was  $94^{\circ}$  on October 8, while on this date the maximum temperature on Mount Tamalpais was  $88^{\circ}$ , and at Point Reyes  $74^{\circ}$ . The lowest temperature recorded during the year on the mountain was  $23^{\circ}$ , on February 4, and on the same date  $34^{\circ}$  at San Francisco and at Point Reyes. The minimum temperature was, therefore,  $11^{\circ}$  lower at the higher station. As has been elsewhere stated, during summer months there is very frequently, owing to the fog, a cooling of  $11^{\circ}$  at the lower station. In all of these instances the retarding influence of the water is apparent, in summer the temperature near the sea remaining cool, and comparatively warm in winter.

Including every day in the month of June there was found to be a mean daily difference of  $11.4^{\circ}$ , or in other words from the data obtained by means of this mountain station, checked by data from Point Reyes and Mount Hamilton, the temperature rose at the rate of  $1^{\circ}$  for every 203 feet of elevation. This increase held at least up to 2,380 feet.

If we consider only those days in the month (twenty-four) when there was a rise with elevation, we have for the mean daily difference in temperature between Mount Tamalpais and San Francisco  $15.3^{\circ}$ , i. e., the temperature rises  $1^{\circ}$  for every 155 feet elevation. This may be adopted as a working normal summer-day gradient.

For days when there was a decrease in temperature with elevation, six in all, we find a difference of  $5.9^{\circ}$ , or there was  $1^{\circ}$  fall for every 402 feet, which, it may be noted, is not quite as steep a gradient as values generally given in text-books,  $1^{\circ}$  for every 300 feet.

We notice first that periods of rainy or cloudy and cold weather occur when the surface temperatures are higher than those of the upper level. It would seem as if at these times the different air strata from sea level to 2,500 feet had been intermingled to some degree and the cold layer usually existing close to the surface had been temporarily displaced.

Fogs seem to occur at times of steep inverted gradients; in other words, when the temperature of the 2,500-foot level is considerably higher than at sea level.

The conclusion to be drawn from what precedes is that the summer fogs of San Francisco result from the chilling of the upper warm air over the ocean by the water, particularly the cold current close to the shore. The strong indraft through the Golden Gate on summer afternoons (see charts of hourly wind velocity, 3 to 7 p. m., fig. 6) carries with it the fog. The movement of the lower fog-laden air eastward and into the valley is compensated by a westward air movement at higher levels. The great difference of temperature between the valley and the ocean, often  $50^{\circ}$  within as many miles, is probably the prime factor in controlling the circulation.

The mountain, as might be supposed, is the drier station, the mean relative humidity being 59 per cent, while it is 83 per cent at San Francisco. Especially during the summer months is the difference noticeable, and, doubtless, it is this dryness which causes such an agreeable "change of climate" to visitors at this season. The difference may perhaps be stated more clearly in this way: The weight of water vapor per cubic foot varies from 1.9 grains to 3.5 grains on the mountain during the year, while at San Francisco it varies from 3.3 grains to 4.4 grains. The average hourly wind velocity seems to increase with elevation, the values for the mountain station far exceeding those of the lower station. The maximum velocities recorded are, respectively, 91 and 47 miles per hour. The total wind movement was 177,017 miles at Mount Tamalpais and 96,602 miles at San Francisco.

The following notes on "Fog at Mount Tamalpais" are reprinted from the Monthly Weather Review, November, 1900, and January, February, and March, 1901:

In fig. 21, Plate I, is shown perhaps the most common type of fog. It may be of interest to compute roughly the weight of water vapor existing under such conditions. From a number of records, a fair average dew-point temperature is  $51^{\circ}$  F. ( $10.6^{\circ}$  C.). It is estimated that an area 10 miles east and west and an equal distance north and south is covered with fog. The upper level of the fog may be taken as half a mile. If the fog were solidly packed, we could not be much in error if we estimated its bulk at 50 cubic miles.

There are, therefore,  $5280^3 \times 50$  cubic feet of water vapor at a mean temperature of  $51^{\circ}$  F. A cubic foot of vapor at this temperature weighs 4.222 grains, and we therefore have as a gross weight 2,219,535 tons of 2,000 pounds each. But most generally the fog disappears between sea level and 1,200 to 1,500 feet altitude, and there are also wide swaths or channels fog free. The amount given above, therefore, would need to be cut in two, and a liberal estimate of the weight of the water vapor in a fog outside the Heads is 1,000,000 tons. This is carried through the Golden Gate by westerly winds, blowing 22 miles per hour, from 1 to 5 p. m.

For each square mile of surface there would be about 10,000 tons of water vapor and for each acre about 15.63 tons. This is equivalent to a rainfall of 0.14 inch.

In Waldo's Modern Meteorology<sup>a</sup> an example in the use of Hertz's graphical tables for following the changes in a given quantity of water vapor under varying conditions is given. With little change, the problem will apply in this case.

FIG. 20.—Fog service at San Francisco. Corner of large map standing in main corridor of Ferry Building. By means of frequent reports from Point Reyes and Mount Tamalpais the extent and character of fog over Drakes Bay, the roadstead, and the Gate itself are known in the city.

At San Francisco the mean actual pressure is 29.87 inches (758.7 mm.) and at Tamalpais 27.55 inches (699.8 mm.); the elevation of the latter station is 724 meters, and the former is practically at sea level.

With a pressure of 750 mm. and a temperature of  $27^{\circ}$  C. ( $80^{\circ}$  F.), a given mass of air, half saturated, lifted upward under adiabatic conditions, will not change its initial 11 grams of water contents per kilogram until at an elevation of 640 meters, when condensation would begin. At an elevation of 700 meters, the pressure being 687 mm., the temperature would be  $19.3^{\circ}$  C. ( $67^{\circ}$  F.).

At 640 meters the dew-point would be  $13.3^{\circ}$  C. ( $56^{\circ}$  F.) or  $2.5^{\circ}$  C. lower than the initial dew-point  $15.8^{\circ}$  C. ( $60^{\circ}$  F.), the difference being due to the increased volume. At 1,000 meters the temperature would be  $8.2^{\circ}$  C. ( $49^{\circ}$  F.), or at a rate of  $0.51^{\circ}$  C. decrease per 100 meters elevation.

It is pointed out, however, that in all theoretical values the assumption is made that the kilogram of mixed air and water vapor retains its mass unchanged, but this can not be the case with a mixture in free air performing a journey of any extent. It is also to be remembered that in the actual case before us the horizontal movements of the given mass would be of far more significance than the vertical movements.

In Von Bezold's third paper on the "Thermodynamics of the atmosphere" (see *Mechanics of the Atmosphere*, pp. 257-288) the effect of mixing different air masses is considered. If two masses of saturated air at  $0^{\circ}\text{C}$ . and  $20^{\circ}\text{C}$ ., respectively, and at 700 mm. pressure are thoroughly mixed, the greatest amount of rainfall that can occur is 0.75 gram per kilogram of air and water vapor. The temperature of the mixture will be  $11^{\circ}\text{C}$ . ( $52^{\circ}\text{F}$ .). The warmer mixture would have yielded the same amount of rainfall by raising it 310 meters or cooling it  $1.6^{\circ}\text{C}$ . by elevation and  $0.8^{\circ}\text{C}$ . by contact.

Direct cooling by contact or radiation is shown by Von Bezold to be more efficient as a cause of rainfall than cooling by mixture, but in the production of fog it is probable that cooling by mixture (except in the case of ground fogs) is the most important factor to be considered. It is to be noted that reverse pressures should also be studied, for perhaps a close watch upon the conditions prevailing when fog is rapidly dissipating might conversely throw light upon the order and relative importance of the three ways of cooling, viz, mixture, expansion, and radiation.

Von Bezold's deductions may be thus summarized: More vapor condenses when a stream of air and vapor at low temperature impinges on a mass of warmer air than with reversed conditions. Ocean fogs as a rule form when cool air flows over warm, moist surfaces, but in the case under discussion, where the ocean surface temperature is  $13^{\circ}\text{C}$ . ( $55^{\circ}\text{F}$ .) and the air temperature may reach  $27^{\circ}\text{C}$ . ( $80^{\circ}\text{F}$ .), it is evident that the above does not hold. It is more probable that condensation is the result of the sharp temperature contrasts at the boundaries of certain air currents having different temperatures, humidities, and velocities, and that the contours of the land play an important part in originating and directing these air currents. The summer afternoon fogs of the San Francisco Bay region, then, are probably due to mixture more than radiation or expansion. The winter tule fogs of the Sacramento and San Joaquin valleys are probably pure types of radiation fog, where the process of cloud building is from the cooled ground upward. Occasionally in summer, when the warm air has been pumped out of the valleys and there is rapid radiation, ground fog forms. An illustration of this is given in fig. 22, Plate I, where fog covers a number of valleys. Summer sea fog is shown in fig. 23, Plate II, and, as said above, is probably due to mixture. The wave motions or Luft Wogen of Von Helmholtz are shown in fig. 24, Plate II, and also the surgings or splashings, where a certain condensation results from the mechanical uplifting.

In several papers presented to the Royal Academy of Sciences of Prussia, Prof. H. von Helmholtz has discussed the conditions which must occur in the atmosphere where strata of different densities lie close together, with particular reference to the billow and wave effects near the limiting surfaces of the strata.

"It appears to me not doubtful,"<sup>a</sup> says Helmholtz, "that such systems of waves occur with remarkable frequency at the bounding surfaces of strata of air of different densities, even although in most cases they remain invisible to us. Evidently we see them only when the lowest stratum is so nearly saturated with aqueous vapor that the summit of the wave, within which the pressure is less, begins to form a haze."

It is probable, as Helmholtz states, that conditions favorable for the origin and propagation of air waves often exist, but with the exception of certain cloud forms it is seldom that the meteorologist has an opportunity to see this wave action clearly defined. It therefore seems of importance to present a few photographs showing the actual wave effects produced probably by the sharp contrasts of air currents of different densities in the vicinity of Mount Tamalpais.

It is thought that in the photographs of fog billows (Plates III and IV) there is evidence of the movement of rectilinear waves propagated, with little change of form and velocity, along the bounding surfaces of the different air strata.

With a wind velocity of 10 meters per second, which nearly corresponds with the mean velocity of the inflowing colder current (the average summer afternoon velocity of the wind through the Golden Gate is about 22 miles per hour), the wave length,  $\lambda$ , is determined by Von Helmholtz to be about 900 meters (2,950 feet). The wave lengths shown in the various fog photographs herewith are of corresponding magnitude and vary, it is estimated, from 100 to 2,000 meters. Helmholtz states further:<sup>b</sup>

"Since the moderate winds that occur on the surface of the earth often cause water waves of a meter in length, therefore the same winds acting upon strata of air of  $10^{\circ}$  difference in temperature maintain waves of from 2 to 5 kilometers in length."

Equations for the velocity of propagation and the diminution of the speed with a change of the depth of the lower stratum and a discussion of the energy of the waves are given for special cases. It is also pointed out that the elevations of the air waves can amount to many hundred meters, and that precipitation could thus be mechanically brought about. The same wind can excite waves of different lengths and velocities, and the interference and reinforcement may perceptibly modify the wave form. One of the processes by which waves of great height can be formed is thus pointed out by Helmholtz, namely, where two wave summits of different groups of waves reinforce each other. The wave height may be so great that foaming is produced. Such long and deep waves may have a bearing on the explanation of certain local and nonperiodic disturbances.

The demonstrated existence of these air billows and waves is important also in connection with the transmission of other air waves. It is well known that sound waves are reflected and refracted in a marked degree in the vicinity of fog banks, fog walls, and fog billows. The inaudibility of fog signals from sirens is one of the greatest sources of danger and anxiety in navigation. Any increase in our knowledge of the dispersion and aberration of these fog signals will be hailed with joy by many thousand travelers. In the vicinity of San Francisco, as evidenced by the

<sup>a</sup> See Abbe's *Mechanics of the Earth's Atmosphere*, p. 94.

<sup>b</sup> See *Mechanics of the Earth's Atmosphere*, p. 103.

series of photographs accompanying these papers, the opportunities for studying the general aberration of sound waves in fog are excellent. It is our earnest hope that in due time some experimental work in this direction may be undertaken at the observatory on Mount Tamalpais. Some very strange effects have already been noticed with regard to the noise of a train when traversing different air strata.

Zones of audibility appear to be quite sharply marked, even after making allowance for the many canyons and "mesas" (tablelands). On foggy days these zones are greatly modified. In addition to changes in density and temperature which sound waves would experience, there are changes due to the movement of the sound-conveying medium. The strong air currents moving toward the listener increase the frequency of vibration and raise the pitch, conversely the air currents moving away from the listener flatten the note.

There have been several instances on nights without fog where ordinary sounds have been heard distinctly at a distance of nearly two miles. On other occasions it has been possible to obtain echoes from hills distant one-half mile or more when the intervening valley was covered with fog. The echoes could not be heard when the fog was absent.

The accompanying photographs may throw light upon the much-discussed question of the abnormal aberration of fog signals. It will be remembered that Prof. Joseph Henry, who for twelve years served as chairman of the Light-House Board, thought that the wind played a more important part in the abnormal aberration of sound waves than the so-called acoustic clouds described by Professor Tyndall. It is probable that up to a certain point both explanations may hold, but the wind is seemingly the more active factor in most cases. Sound moving with the wind is refracted downward and moving against the wind refracted upward.<sup>a</sup>

From the great mass of conflicting evidence it appears that a homogeneous atmosphere without the internal stream lines (see reference to this under "Air drainage," in previous pages) conveys sound waves very well; but this is not the usual condition. Under normal conditions the mass of air within a mile or two of a light-house and extending upward half a mile is neither still nor homogeneous. One of the main purposes of the accompanying fog photographs is to show the stratification, faulting, and upheaval effects due to differences of temperature and density caused by extensive and rapidly moving currents. Of course the aberration of audibility of fog signals due to changes of the sound-conveying medium is not to be confounded with the aberration in audibility due to topographical features and the normal reflection and refraction of sound waves. Probably within a short distance of every light-house there are zones or points of inaudibility due to the latter causes. An excellent illustration of this can be found in a paper on Fogs and Fog Signals of the Pacific Coast, by Ferdinand Lee Clarke.<sup>c</sup> It is there shown that the sirens around the Golden Gate and in San Francisco Bay are inaudible at certain points. Here, there is an interference of sound waves due to numerous natural reflections.

It has been suggested that if the fog signals at Lime Point and at Point Bonita were properly attuned a resulting harmonic might be heard at certain points instead of the weakened noise now heard. We need measurements of the energy producing the air pulsation, the proportionate energy reaching the ship or given point, and the rate of expenditure with different conditions of density and air movement. By the employment of suitable resonators the pulsations reaching the ship might be more easily detected. With the introduction of etheric telegraphy it would almost seem practicable to obtain by this same principle of resonance electromagnetic signals, and by comparing the time intervals between these and the sound waves in air or transmitted through water the distance apart of the vessels or the distance from the shore might be determined within a few feet.

The velocity of sound, it is generally stated, is within wide limits practically independent of both intensity and pitch. In dry air at 0° C., according to Rowland, the velocity of sound propagation is 331.78 meters (1,090 feet) per second. In water vapor at 10° C., according to Masson, the velocity is about 402 meters (1,318 feet) and at 96° C. 410 meters (1,345 feet) per second. In water at 10° C. the velocity is about 1,435 meters (4,708 feet), in copper about 3,560 meters, and in glass from 5,000 to 6,000 meters.

The velocity is proportional to the square root of the absolute temperature, as given by the formula:

$$a = a_0 \sqrt{1 + \frac{\theta}{273}}$$

where  $a$  = velocity of sound

$a_0$  = velocity of sound at 0° C

The velocity of sound propagation in dry air is therefore about 37 times more rapid than that of the average summer afternoon winds (20 miles per hour), which blow through the Golden Gate with such regularity and which are the prime disturbing factors in the circulation of the air in this vicinity. The question of refraction of sound in free air has been independently studied by Stokes,<sup>a</sup> Taylor,<sup>b</sup> Henry,<sup>c</sup> Tyndall,<sup>d</sup> and Reynolds,<sup>e</sup> and many of the puzzling phenomena connected with the aberration of sound can be demonstrated to be caused by the bending of the sound beams in traversing air strata of varying temperatures and motions. The most efficient cause of loss of audibility is wind. The loss is not due to an actual retardation of the sound waves by the movement of the air so much as to a refraction of the wave front upward from the earth. Sound traveling with the wind is bent downward and traveling against the wind is bent upward. Knowing this, we are able, by lifting the position of the hearer,

<sup>a</sup> Report British Association, 1857

<sup>b</sup> Smithsonian Report, 1875

<sup>c</sup> Smithsonian Report, 1877

<sup>d</sup> Philosophical Transactions, 1874.

<sup>e</sup> Philosophical Transactions, 1876.

sometimes to make sound audible against the wind. Thus Henry shows that a sound moving against the wind, inaudible to the ear on the deck of a vessel, could be heard at the masthead. Reynolds's experiments even more conclusively demonstrate the bending of the wave front downward as a rule when moving with the wind and upward when moving against the wind.

The accompanying photographs, Plate V, figs. 27 and 28, show air strata moving with varying velocities. As a rule the upper currents have the greater velocity, but not infrequently this condition is reversed. In such cases audibility should be favored even by an opposing wind, and this is sometimes found to be the case. Thus far we have alluded only to the refraction of the wave fronts due to varying air velocities; but the varying temperatures of the different air masses will also affect the relative audibility. Reynolds instances a marked case, where, owing to a thorough cooling of the lower air strata, and presumably a marked inverted temperature gradient, the audibility was excellent, the sound being refracted downward, and all objects "looming," as it were. It is even possible to work out the retardation or acceleration of the wave front with the degree of variation in temperature. Finally, it may be that the temperature and the air motion may act together to refract downward the sound wave, and it may also happen that the one influence may oppose the other. Thus Reynolds gives an example where, with a heavy dew on the ground, sound could be heard equally well against a light wind as with the wind—

"Showing that the upward refraction by the wind was completely counteracted by the downward refraction from the diminution of temperature. This was observed not to be the case when cloudiness at night prevented terrestrial radiation." (Proc. R. S., 1874.)

The presence of large quantities of condensed water vapor brings us to the question of refracting surfaces and the reverberation of the sound rather than its velocity.

When a sound wave travels over a perfectly smooth surface, such as a glassy sea, or a sharply outlined plane of condensation, the intensity of the sound does not diminish with the usual rapidity. In discussing the propagation of sound in whispering galleries, Rayleigh<sup>a</sup> shows that the abnormal loudness is not confined to a point diametrically opposite that occupied by the speaker, but that there is a bending or clinging of the sound waves to the surface of the concave wall. Sonorous vibrations at fog surfaces and cloud surfaces may behave in a somewhat similar way, and it is probable that the curvature of the surface is not of as great importance as the comparative smoothness of the surface. Probably the roll of thunder is an excellent illustration of continued reverberation at cloud surfaces.

#### WRECK OF THE PACIFIC MAIL STEAMSHIP "RIO DE JANEIRO."

Any memoir upon the fog of San Francisco Bay would be incomplete without a reference to one of the most remarkable of marine accidents. On the morning of Friday, February 22, 1901, the Pacific Mail steamship *Rio de Janeiro* ran upon the Fort Point Reef during a fog. Within fifteen or twenty minutes from the time of striking the vessel sank, and of the 210 persons on board 130 were lost. Another statement, purporting to be official, makes the total number aboard 207 and the lost 127.

The following facts are obtained chiefly from the statements of Pilot F. W. Jordan. The ship's master, Capt. William Ward, went down with the vessel. The pilot boarded the *Rio de Janeiro* in the vicinity of the 9-fathom buoy, near the bar buoy, and anchored in 13 fathoms at a little before 6 o'clock Thursday night, February 21. The weather being foggy, the ship remained at anchor till about 4 a. m., one hundred and twentieth meridian time, when the fog lifted and the Cliff House light could be seen, but not the Point Bonita light. Preparations were in progress to steam into the harbor, when a dense fog came out from the Golden Gate, obscuring everything. There is some difference of testimony as to whether the captain or the pilot gave the orders to proceed in the fog, but the vessel was started on a northeast course with Lime Point straight ahead, steering by the whistle. The pilot expected to get an echo of the ship's whistle from Point Diablo, but heard none. The course was changed north-northeast with the intention of running close to Lime Point. The vessel was not moving at full speed and was subject to a strong cross current, which, apparently acting at right angles to the length of the vessel, carried the ship to the south, far out of the proper course. The first officer was standing on the starboard side listening for the Fort Point bell. No soundings, however, were taken. The vessel struck a short distance to the southwest of the Fort Point light. At the moment of striking the pilot saw the white flash at Fort Point and heard the Fort Point bell.

The pilot had had eleven years' experience in the harbor and was considered one of the most capable pilots in San Francisco. He had never previously met with an accident. There appears to be no doubt of the existence of the strong cross current, inasmuch as other vessels entering

<sup>a</sup>Theory of Sound, vol. 2, sec. 287.

the harbor about the same time on the same morning came near going on the rocks. The Pacific Mail Steamship Company has a rule that vessels must not enter or leave a harbor when fog prevails. On the morning in question the fog lifted for a few moments and then settled down again; but by 9 a. m., local time, the fog had dissipated. The rest of the day was clear and balmy and the water as smooth as a mill pond.

The vessel struck about 5.30 a. m., with the pilot and captain on the bridge, the first officer on the starboard side of the bridge listening for the bell, and the second officer at the telegraph. When the vessel struck, the captain blew the danger whistle, a long blast. Ordinary fog blasts (long enough to count six or seven) had been blown previously.

The details of the accident, particularly with reference to the whistles, the course steered, and the motion of the current, are given, because from such evidence as can be obtained at this writing it appears that even after the vessel struck the sound of the whistle was not heard plainly at Fort Point, not more than half a mile distant, where a lookout of the life-saving station was on duty and where a life-saving crew could have hurried to the rescue and probably reached the ship within five minutes, without doubt saving many of those whose lives were lost. There was also a sentry walking post within a short distance of the lookout. It is stated that some soldiers heard voices and also a whistle, but the evidence is very conflicting, and it seems improbable that if the long danger blast was clearly heard it should pass without notice and subsequent action.

The Weather Bureau records show that about the time of the accident a mongrel tule fog prevailed over the Bay of San Francisco. At Mount Tamalpais the weather was clear, with a wind of 13 miles per hour from the northwest. At San Francisco dense fog prevailed, with little, if any, wind. The wind vane at the Mills Building indicated a southwest wind blowing about 1 mile per hour. From 1 a. m. to 6 a. m. but 9 miles of wind were recorded.

When all is said and done it appears that the fog was the prime factor in causing the loss of the vessel. Owing to the aberration of the sound waves in the fog the pilot was unable to hear the fog signals from either Point Bonita or Lime Point to the north, or the tolling of the bell at Fort Point to the east and north. It has not, however, been shown that the bell was certainly ringing. The Lime Point whistle has great penetrative power. The fog bell at Fort Point is 40 feet above the water, and should be heard for at least a mile. It is supposed to be struck every ten seconds. It is a strange fact that in a paper upon the Fogs and Fog Signals of the Pacific Coast, by Ferdinand Lee Clark, published in 1888, there should occur this statement concerning the fog bell at Fort Point.

In point of fact it is said to be hardly ever heard except when too late to be of use \* \* \* If mariners depended upon its sound to tell them how near they were to the point, they would generally have no time after hearing it to clear the danger.

The loss of the *Rio de Janeiro* proves that the bell at Fort Point in its present position is sometimes of little value.

The temperature at the time of the accident was 50° F. at sea level and 52° at a height of 2,500 feet. The thickness of the fog probably did not exceed a few hundred feet; and, as indicated above, it was a land fog rather than a sea fog.

As a general thing the reflected sounds from Point Bonita and Lime Point are heard better on the south side of the channel. On the accompanying rough sketch of the channel the lines of natural reflection are drawn and also the zones of inaudibility.

It is not difficult to account for the failure of the echo of the ship's whistle from some portion of the northern shore, as the distance of the vessel from Point Diablo was too great. The sound waves from the fog whistle at Lime Point, however, should have been heard, and as the moderate southwest wind would tend to cause a deflection of the sound wave upward it is possible that while the sound was inaudible on the deck of the vessel it might have been heard by a lookout at the masthead.

The catastrophe furnishes a remarkable illustration of the utter helplessness of a vessel in fog, despite lights and fog whistles. It would seem that under such conditions nothing short of some method of fog dissipation will suffice.

It has occurred to the writer, although the suggestion may prove of no value in practice, that if a strong sound had been made under water by some automatic contrivance at either Lime Point or Point Diablo, and the *Rio de Janeiro* been provided with some suitable device rendering audible the sound wave through the water, the strong cross current would have facilitated the passage of the sound and a zone of audibility would have been established in the water, while in the atmosphere above the fog signals would have been inaudible.

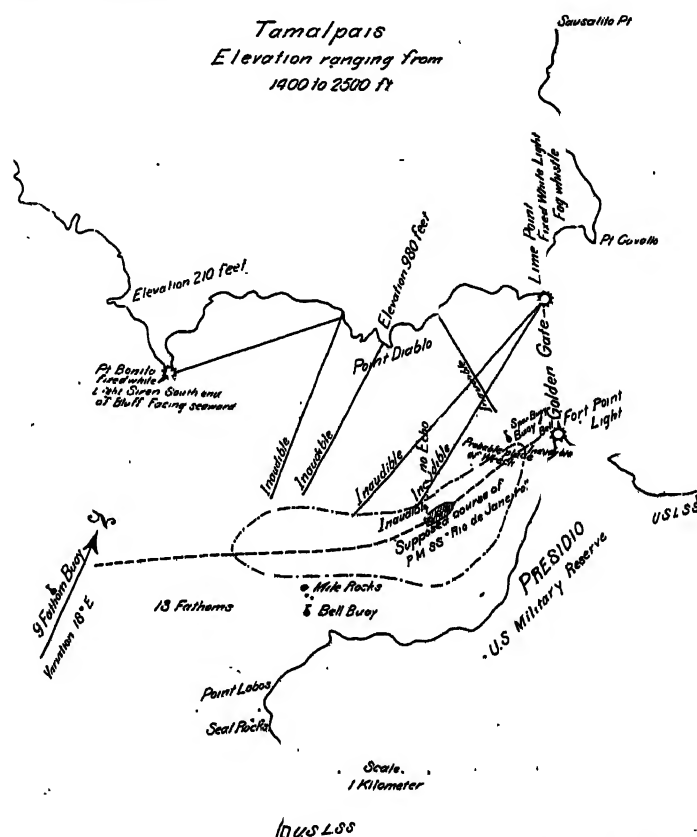

FIG. 81.—Probable conditions at time of wreck, February 22, 1901.

The accompanying photographs, Plate VI, are submitted to show that to a certain degree the captain and the pilot were justified in assuming that they might soon run into areas free from fog. As a matter of fact on the day in question the fog soon disappeared and a delay of perhaps two hours would have prevented the accident. It should not be forgotten, however, that the captain was unwilling to enter the harbor during the fog Thursday night, and that the vessel remained at anchor for a period of nearly twelve hours and was thereby exposed in a large degree to the danger of collision.

## THUNDERSTORMS.

It is sometimes stated that thunderstorms are exceedingly rare in California and that lightning is almost unknown along the coast. And it is generally believed that the Pacific coast, or at least the southern half of it, is a region free from thunderstorms and the damage by lightning is practically an unknown quantity. In the eastern part of the United States considerable damage is done by thunderstorms between the months of April and September. In California thunderstorms may occur during any part of the year. In a discussion of 356 reports of thunderstorms in California from July, 1895, to August, 1896, we found that there were 3 dates in July on which storms occurred, 6 in August, 8 in September, 10 in October, none in November, 3 in December, 5 in January, 2 in February, 3 in March, 9 in April, 15 in May, 6 in June, 22 in July, and 17 in August.

Some of the storms covered very large areas and were quite generally reported, such, for example, as October 14-15, 1895; May 29 and August 28-29, 1896. Examining certain marine reports, it appears that on January 25, 1896, thunderstorms prevailed in the Pacific Ocean, and it is not surprising to find that a day or two later thunderstorms were reported in California. These storms apparently moved inland from the ocean. There is another class of storms, however, apparently connected with the general low-pressure movements from the southwest. A condition favorable for thunderstorms in the valley of the Colorado in July and August is frequently followed within ten or twenty hours by thunderstorms along the Sierra.

The following table shows the distribution of thunderstorms in California during the year of 1895-96:

DISTRIBUTION OF THUNDERSTORMS.

During the summer months in the great valleys and canyons of the eastern and southern portions of the State thunderstorms frequently occur during the afternoon and evening hours.

John Muir, writing in the Atlantic Monthly for September, 1901, on the Big Trees, makes the following statement. "Most of the Sierra trees die of disease. Thus the magnificent silver firs are devoured by fungi, and comparatively few of them live to see their three hundredth birth year. But nothing hurts the Big Tree. I never saw one that was sick or showed the slightest sign of decay. It lives on through indefinite thousands of years, until burned, blown down, undermined, or shattered by some tremendous lightning stroke. No ordinary bolt ever seriously hurts Sequoia. In all my walks I have seen only one that was thus killed outright.

"Lightning, though rare in California lowlands, is common on the Sierra. Almost every day in June and July small thunderstorms refresh the main forest belt. Clouds like snowy mountains of marvelous beauty grow rapidly in the calm sky about midday and cast cooling shadows

and showers that seldom last more than an hour. Nevertheless, these brief, kind storms wound or kill a good many trees. I have seen silver firs 200 feet high split into long peeled rails and slivers down to the roots, leaving not even a stump, the rails radiating like the spokes of a wheel from a hole in the ground where the tree stood. But the Sequoia, instead of being split and slivered, usually has 40 or 50 feet of its brash, knotty top smashed off in short chunks about the size of cord wood, the beautiful rosy-red ruins covering the ground in a circle 100 feet wide or more.

"I never saw any that had been cut down to the ground, or even to below the branches, except one in the Stanislaus Grove, about 12 feet in diameter, the greater part of which was smashed to fragments, leaving only a leafless stump about 75 feet high. It is a curious fact that all the very old Sequoia have lost their heads by lightning. 'All things come to him who waits,' but of all living things Sequoia is perhaps the only one able to wait long enough to make sure of being struck by lightning. Thousands of years it stands ready and waiting, offering its head to every passing cloud as if inviting its fate, praying for heaven's fire as a blessing, and when at last the old head is off another of the same shape immediately begins to grow on."

During the months of July and August, 1896, thunderstorms were unusually frequent. During July storms occurred at Bodie on the 4th, 5th, 21st, 23d, and 25th; at Crafton on the 4th; at Descanso on the 8th, 10th, 12th, 13th, and 24th; at Edmanton on the 5th, 15th, and 16th; at Greenville on the 5th, 16th, 24th, and 25th; at Guinda on the 5th; at Laporte on the 5th and 15th; at Lodi on the 25th; McMullen on the 3d, 4th, 7th, 12th, 17th, and 24th; at Middletown, 29th; Paso Robles, 4th; Peachland, 10th; Pichaco, 9th, 12th, 13th, 14th, 15th, 18th, and 24th; Pilot Creek, 5th, 15th, 16th, 25th, and 26th; Placerville, 25th; Quincy, 15th; Reedley, 4th, 5th, 22d, and 24th; Rio Vista, 10th; Rosewood, 5th, 15th, 25th, 27th, and 28th; Santa Cruz, 22d; Shasta, 17th, 26th, 27th, and 28th; Turlock, 4th and 25th; Ukiah, 10th and 29th; Upper Silver Lake, 10th, 27th, 28th, and 29th; Washington, 15th; West Point, 25th; Wire Bridge, Yreka, 25th, 26th, 27th, and 28th.

*August, 1896.*—Bodie, 12th, 17th, 18th, 19th, and 22d; Crafton, 16th; Crescent City, 29th; Durham, 30th; Descanso, 14th, 15th, and 27th; Edmanton, 22d, 28th, and 30th; Follows Camp, 16th; Folsom, 22d and 30th; Grass Valley, 22d and 30th; Greenville, 22d, 23d, 24th, 28th, and 29th; Iowa Hill, 29th; Laporte, 22d, 28th, and 29th; Los Gatos, 19th; McMullen, 20th and 29th; Middletown, 29th and 30th; Newcastle, 18th and 22d; Niles, 19th; North Bloomfield, 22d; Orangevale, 22d; Peachland, 19th and 20th; Pichaco, 14th, 19th, 26th, 27th, and 28th; Pilot Creek, 17th, 22d, and 29th; Placerville, 22d; Roseville, 21st; Rosewood, 19th, 20th, 23d, 28th, 29th, and 30th; Sacramento, 22d; San Jose, 19th; Santa Clara, 20th; Santa Cruz, 18th; Shasta, 20th and 27th; Susanville, 19th and 23d; Ukiah, 22d; Ventura, 17th; Wire Bridge, 22d; Yreka, 19th, 20th, and 21st.

*September, 1896.*—Edmanton (distant) on the 20th and 28th; at Grass Valley on the 28th; at Iowa Hill on the 28th; at Los Gatos on the 21st; at Lime Kiln on the 5th; at Laporte on the 2d, 3d, 6th, 20th, 22d, and 28th; at Upper Lake (Ma. Tel. Vineyard) on the 22d; at McMullen on the 20th; at North San Juan on the 28th; at Pilot Creek on the 5th and 28th; at Rio Vista on the 22d; at Reedley on the 5th; at Rosewood on the 22d; at San Jacinto on the 4th, 5th, and 29th; at Shasta on the 7th; at Snedden on the 5th; at Tulare on the 5th, 19th, and 22d; at Turlock (distant) on the 5th; at Yreka on the 6th, and 22d; at Isabella on the 5th.

*October, 1896.*—On the 20th, at Bodie; on the 25th, at Briggs Vineyard; on the 27th, at Descanso; on the 16th, at Famosa; on the 25th, at Guinda; on the 27th, at Las Fuentes Rancho; on the 25th, at Peachland; on the 16th, at Paso Robles; on the 27th, at Claremont; on the 16th, at Reedley; on the 25th, at Sacramento; on the 25th, at Ukiah; on the 25th, at Winters.

During November and December there were few, if any, thunderstorms in California.

The following notes relative to the character of the storms may be of interest:

On January 26, 1896, the plant of the Haywoods Electric Light Company was struck by lightning. The electrician, Mr. J. Putnam, is reported as saying:

I was not more than 20 feet away from the dynamo when the crash came, and it seemed as if the lightning filled the whole building. The flames shot out from the dynamo about 8 feet, and the wires, magnets, and mica were thrown all over the place. I instantly ran to the switchboard and disconnected the wires, and there was no more

light that night. The accident was a very simple one, and one that will be guarded against in future. The lightning was conducted to the machine by one of the wires, and of course the dynamo was instantly overcharged and burnt \* \* \* There is one hole and no trace of the missing metal. The wires that surrounded the magnets were so highly charged that they flew in all directions, and when the mica was free it fell around in showers. It will take several days to fix the wrecked machine. If I had been oiling that dynamo when the lightning struck I would have been charred to a cinder as rapidly as that piece of iron was burned.

At Folsom, on the 24th of April, lightning struck the lines of the Electric Light and Power Company five times, and the machines went out of step at each stroke. The lightning arresters were burned and discolored. On April 9, at Ontario, two strokes of lightning entered the electric power house. Wires were burned and a coat belonging to one of the employees set on fire.

The first stroke, it is stated, came from overhead, while the second struck the wires miles away and came in when the sky was clear overhead. Lightning conductors were under the floor, but had not been connected, as it was thought there would be no use for them. After the first stroke they were connected. Notwithstanding, the second stroke did more damage in the power house than the former, showing that it was much the heavier charge.

The Fresno Republican of October 17 reports that—

A heavy thunderstorm in the hills caused a shutting down last evening of the entire electric plant of the San Joaquin Electric Company for twenty minutes. The lightning passing over the lightning arresters caused the points to become welded together, forming a short circuit across the two lines. Occurring at a time when the city was in darkness the delay in repairing was greater than it would have been during the day. No great damage was done to the machinery.

In the city of San Francisco houses and barns have been struck and some damage done. A large cypress tree on the southeast corner of Broderick and Green streets was riven from branch to root. A very large branch was torn off and thrown some little distance. On August 19, 1896, the signal-flag pole at Point Lobos was struck by lightning and badly damaged. The pole was 60 feet high, and the upper 20 feet were so torn that a new pole was necessary. Large splinters of wood were thrown over 150 feet away. Lights were burned out at the terminus of the Sutro Electric Railroad, and other damage done in the vicinity.

On November 7, 1900, four distinct flashes of lightning, accompanied by loud thunder, were recorded at the Weather Bureau office at San Francisco. The first flash was at 10.15 a. m. and the others at 10.27, 10.30, and 10.42 a. m. The average interval between the flash and the thunder was about six seconds. On December 14, 1900, during a sharp thunderstorm a flash of lightning struck the relief gasometer at Bay and Buchanan streets, containing 260,000 cubic feet of gas. The tank was demolished and the gas ignited. The flame was carried by the gale a distance of 250 feet, and the roar could be heard above the noise of the storm. The officials of the gas company estimated the loss at \$6,000.

On October 3, 1901, at Houghton ranch, near Thomas Creek, about 12 miles west of Corning, Cal., during a heavy thunderstorm Coutea Jobe, aged 20 years, was struck by a flash of lightning and killed.

The light-house on the Southeast Farallon Island was once struck and a small amount of damage resulted.

*January, 1898.*—At Hill Ranch on the 31st.

*February, 1898.*—At Fort Bragg on the 20th, Grass Valley 7th, Iowa Hill 27th, Lodi 7th, Rosewood 7th, 20th, and 27th, Sacramento 7th, Shasta 24th and 27th, Wire Bridge 7th and 27th.

*March, 1898.*—At Folsom and Grass Valley on the 9th, Hill Ranch 25th, Iowa Hill 9th and 17th, Limekiln, Oleta, Placerville, and Pilot Creek 9th, Rosewood 16th, West Point 9th, Wire Bridge 9th and 26th.

*April, 1898.*—At Bowmans Dam 29th and 30th, Descanso 14th, Durham 30th, Edmanton 29th, Elsinore 14th, Folsom 30th, Grass Valley 29th, Laporte 29th and 30th, North Hill vineyard 6th, Oleta and Pilot Creek 30th, Quincy 29th, Shasta 27th, Susanville and West Point 30th, Yreka 20th and 22d.

*May, 1898.*—At Bodie on the 11th and 12th, Cedarville 5th, 11th, and 13th, Grass Valley 19th, Rosewood 12th, 17th, and 18th, Shasta 17th and 18th, Susanville 14th, Yreka 5th, 11th, 12th, and 13th.

*June, 1898.*—At Bodie on the 6th, Bowmans Dam 7th and 8th, Cedarville 7th, 11th, and 22d, Edmanton 8th and 9th, Manzanita 10th, Rosewood 1st, 7th, 8th, 9th, 10th, and 11th, Shasta 1st and 8th, Ukiah th.

*July, 1898.*—At Bodie on the 6th and 29th, Descanso 10th, Edmanton 8th, Los Angeles 4th, San Jacinto 3d and 4th, West Saticoy 4th, Yreka 8th and 21st.

*August, 1898.*—At Bodie on the 6th, 12th, and 13th, Cedarville 8th and 13th, Crescent City 28th, Descanso 10th, 15th, 20th, 21st, 22d, 24th, and 28th, Edmanton 28th, Elsinore 9th, 10th, 12th, and 20th, Fallbrook 9th, Greenville 6th and 7th, Laporte 6th, Oleta 7th, Quincy 29th, Rosewood 6th, 13th, 14th, and 31st, San Jacinto 9th and 21st, Shasta 28th, Sierra Madre 9th, Susanville 13th and 29th, Ukiah and Upper Lake 13th, Yreka 6th, 7th, 14th, 28th, and 31st.

*September, 1898.*—At Anada on the 1st, Descanso 8th, Georgetown, Grand Island, Oleta, and Pilot Creek 26th, Rosewood 1st, Susanville 30th, Turlock 26th, Yreka 1st.

*October, 1898.*—At Crescent City on the 1st, Durham 3d, Grand Island 3d and 7th, Greenville 7th and 8th, Lodi 2d and 8th, Oakland and Peachland 7th, Rosewood 3d, Turlock 1st and 8th, Wire Bridge 2d.

*November, 1898.*—At Crescent City, Del Norte County, on the 19th.

*December, 1898.*—At Escondido on the 9th, Fallbrook 8th and 9th, Long Beach 14th, Poway 9th.

*January, 1899.*—At Fallbrook, Irvine, Paso Robles, Ranch House, Santa Barbara, and West Saticoy on the 11th, Oleta on the 20th.

*February, 1899.*—At Berkeley on the 1st and Mills College on the 2d.

*March, 1899.*—At Goldrun on the 12th, Grass Valley 13th, Iowa Hill 12th, Kennedy Gold Mine 28th, Lodi 16th, Oleta 26th, Pilot Creek 12th and 28th, Rosewood and Shasta 24th and 28th, Wire Bridge 13th and 18th, Yreka 28th.

*April, 1899.*—At Grand Island on the 25th, Greenville 21st, Guadalupe 26th, Laporte 21st, Napa 24th, North Bloomfield 27th, North San Juan 24th, 25th, and 30th, Oleta 23d, Pilot Creek and Raymond 30th, Rosewood 1st and 24th, Thermalito 24th and 30th.

*May, 1899.*—At Bodie on the 5th, Bowmans Dam 4th and 18th, Cisco 12th and 18th, Cuyamaca 8th, Delta 5th, Floriston 18th, Folsom 14th, Goldrun 6th, Grand Island 5th and 24th, Greenville 5th and 14th, Iowa Hill 18th and 24th, Lodi 6th, Moreno Dam 8th, North Bloomfield 5th and 14th, North San Juan 6th, Oleta 24th, Placerville 24th, Sacramento 14th, Tehama, Thermalito, and Wheatland 5th, Yreka 24th.

*June, 1899.*—At Folsom, Pilot Creek, and Wire Bridge on the 2d, Susanville on the 1st.

*July, 1899.*—At Cedarville on the 14th, Cuyamaca and Volcano Springs 20th and 21st, Yreka 14th and 15th.

*August, 1899.*—The central and northern portions of the State experienced unusual electrical storms during the first part of the month, that of the 3d being the most severe in the month of August for many years; it was accompanied by rain at some places and by heavy hailstorms at others, but no extensive damage was reported. In the San Joaquin Valley, where the storm was most severe, telegraph and telephone lines were interfered with, fuses were burned out and a few poles were struck by lightning, and at North Hill vineyard two horses were instantly killed. During the storm of the 6th, in the vicinity of Chico six persons were stunned by lightning while riding in a wagon and a young colt was killed. On the 10th, at Susanville, Lassen County, several sheep were killed by lightning. The following stations report thunderstorms on the 3d: Auburn, Bodie, also on the 1st, 2d, 4th and 7th; Elkgrove, Folsom, also on the 4th; Goldrun, Grand Island, Guinda, Iowa Hill, also 2d, 4th, 5th, 6th; Lagrange, Lankershim, Lathrop, Lick Observatory, Lodi, Merced, Milton, Minturn, Napa, North Bloomfield, North Hill vineyard, North San Juan, also 4th and 6th; Palermo, also 5th and 6th; Pilot Creek, also 4th, 5th, 6th; Raymond, Rivista, Sacramento, Shasta, also 16th; Stockton, Upper Lake, Vacaville, Wheatland, Wire Bridge, Woodland. Other thunderstorms were reported as follows: At Boulder Creek on the 4th and 5th, Chico 6th, Covelo 20th, Edmanton 17th, Fort Ross and Grass Valley 4th, Greenville 4th and 6th, Healdsburg 2d, Kono Tayee 1st, Laporte 4th, 6th, 17th, Los Angeles 9th, Oleta 6th, 7th, Orange 9th, Quincy 6th, Rosewood 6th, 7th, Santa Ana 9th, Susanville 4th, 5th, 6th, 10th, 17th, Yreka 13th, 19th.

*September, 1899.*—At Arcadia, Buena Park, Compton, Downey, Irvine, North Ontario, Palm Springs, Ranch House, and Sierra Madre on the 9th. There were also thunderstorms in the mountains near Bakersfield, Downey, Huron, and Tejon Rancho on the 11th.

*October, 1899.*—At Arcadia on the 7th, Crescent City 19th, Cuyamaca and Lamesa 6th, Lodi 11th and 12th, North Bloomfield 12th, North Hill vineyard 11th, North Ontario 6th, Oleta 11th and 12th, Pilot Creek 11th, 12th, and 20th, Ranch House 6th, Reedley 13th, Represa 11th, Rosewood 12th, 21st, and 22d, Shasta 19th and 22d, Stockton 1st, Summit 10th and 11th, Wire Bridge 11th and 12th.

*November, 1899.*—At Crescent City on the 21st, Fall Brook 17th, Lamesa 14th, Oleta 12th and 15th, Placerville 15th, Rosewood 10th

*December, 1899.*—At Berkeley and Fort Ross on the 8th and Crescent City on the 14th, 30th, and 31st.

*January, 1900.*—At Crescent City on the 7th.

*February, 1900.*—At Porterville, Rosewood, Santa Maria, and Yreka on the 18th.

*March, 1900.*—At Bellevue on the 3d, Claremont and Follows Camp 20th, Crescent City 26th, Delta 2d, Edmanton 22d and 25th, Folsom, Grass Valley, Greenville, Laporte, Mokelumne Hill, North Hill vineyard, Oleta, Porterville, Westpoint, and Wire Bridge 22d, Lagrange, Raymond, Redding, Represa, Rosewood, Thermalito, and Wheatland 4th, Moreno Dam 14th, North San Juan 7th, Pilot Creek 21st, Susanville 30th.

*April, 1900.*—At Bellevue, Bodie, Shasta, Susanville, and Yreka 30th, Bowmans Dam 15th, Branscomb, Durham, Edmanton, Grass Valley, Iowa Hill, Johnsville, Lagrange, Lankershim, Laporte, Le Grand, Lodi, Merced, Nevada City, Palermo, Redding, Rosewood, Vina, Visalia, and Wire Bridge 2d, Elsinore 28th, Greenville 25th, 28th, and 30th, Irvine 3d and 27th, Moreno Dam 27th, Oleta 23d, Pilot Creek 2d and 28th, Raymond 3d.

*May, 1900.*—At Bellevue on the 31st, Crescent City, Edmanton, Greenville, Laporte, and Pilot Creek 2d, Folsom, Irvine, Represa, Sacramento, Shasta, Tracy, and Wire Bridge 4th, Rosewood 9th and 10th, Susanville 3d

*June, 1900.*—At Antioch, Brentwood, Campbell, Danville, Jackson, Laporte, Lick Observatory, Lodi, Los Gatos, Milton, Mokelumne Hill, North Hill vineyard, Oleta, Riovista, San Luis Obispo, San Ramon, and Wire Bridge on the 13th, Auburn, Georgetown, and Iowa Hill on the 12th, Cedarville 11th, Cottonwood, Red Bluff, and Shasta 15th, Edmanton 9th, Greenville 9th and 15th, Paso Robles 8th, Pilot Creek 12th to 15th, Rosewood 8th, 13th, and 15th, Susanville 8th and 9th, Tejon Rancho 8th, Yreka 2d, 11th, 15th, 17th, and 22d.

*July, 1900.*—At Bodie on the 31st, Bowmans Dam 21st, Cedarville 20th, 21st, and 29th, Elsinore 20th, Greenville 2d, 21st, and 22d, Laporte and North San Juan 21st, Palm Springs 20th and 31st, Pilot Creek 21st, 22d, and 23d, Rosewood 1st, Summit 20th and 24th, Susanville 2d, 20th, 21st, and 29th, Yreka 20th and 29th.

*August, 1900.*—At Bellevue on the 7th, 14th, 18th, 20th, 22d, and 28th, Bodie 1st, Cedarville 10th, 14th, and 20th, Edmanton 30th, Elsinore and Fall Brook 1st, La Porte 29th, Mammoth Tank 1st, Manzana 31st, Moreno Dam 1st, Oleta 30th, Placerville 30th, Redding 20th, Rosewood 7th and 28th, Shasta 24th, Susanville 19th, Yreka 14th and 21st.

*September, 1900.*—At Branscomb on the 7th, 11th, and 13th, Cedarville 7th and 10th, Cuyamaca 2d, Folsom and Grand Island 12th, Greenville 3d, 10th, 11th, and 12th, Jackson 12th, Lodi 13th, North Bloomfield 11th, 12th, and 13th, North Hill Vineyard 12th, Pilot Creek and Placerville 13th, Redding 4th, 5th, 12th, and 13th, Rosewood 4th, 7th, 11th, and 12th, Sacramento 12th, Santa Barbara 1st, Shasta 4th, Summit 12th, Susanville 3d, Tejon Ranch 1st and 2d, Visalia 2d and 3d, West Point 3d and 12th, Wire Bridge 12th, Yreka 7th, 10th, and 12th.

*October, 1900.*—At Branscomb on the 3d, Crescent City 18th and 23d, Grand Island 28th, Iowa Hill 2d, Keeler, La Porte, and Moreno Dam 11th, Pilot Creek 2d, 11th, and 28th, Redding 11th, Summit 4th, Wheatland 18th, West Point 2d.

*November, 1900.*—At Berkeley on the 7th and 16th, Branscomb 20th, Claremont and Cuyamaca 17th, Grand Island, Grass Valley, and Los Gatos 7th, Los Angeles 16th, Mills College 7th and 16th, Niles 7th, North Ontario 17th, Oakland and San Francisco 7th and 16th, Oleta 19th, Rio Vista 21st, Rosewood 7th, Sacramento 21st, San Bernardino and Soledad 17th.

*December, 1900.*—The following stations reported severe storms, accompanied by thunder, lightning, high wind, and rain, on the 14th: Berkeley, Campbell, Fort Ross, Grand Island, Jackson, Lick Observatory, Merced, Mills College, Modesto, Oakland, Oleta, Peachland, Pilot Creek, Rio Vista, San Francisco, San Leandro, Sonoma, Suisun, Vacaville, West Point, and Wire Bridge; also at Crescent City and Tequisquita Rancho on the 16th, and Le Grand on the 17th.

## LOCAL STORMS.

With nearly every general disturbance there are reports of individual disturbances with more or less damage in limited areas. As a rule the State of California is exempt from marked tornadic disturbances. Severe local storms, however, sometimes occur, but, as stated above, these are chiefly straight-line wind storms. The following illustration, however, seems to show more of the violent gyratory action of the whirlwind than of an ordinary storm, and is therefore given.

## STORM OF DECEMBER 14, 1900.

By J. C. STANTON, voluntary observer.

The storm of December 14 in the vicinity of Rio Vista somewhat resembled a tornado, accompanied by thunder and lightning. The first manifestation seems to have been at Lodi, about 10 miles to the southeast, where considerable damage was done. It then took somewhat of a southwesterly course to Collinsville, where a hay barn was taken up bodily, carried several hundred feet, dropped, and entirely demolished. The building must have been raised perpendicularly, as a large quantity of baled hay which it contained remained intact and unmolested. From this point the storm took a northeasterly course, arriving at Rio Vista about 10.45 a. m., sweeping through the northwest part of the town, unroofing a carpenter shop, blowing down a high board fence, and overturning two windmills at St. Gertrude's Academy. These were strongly constructed, with iron towers, and from their appearance seem to have been twisted off and so badly damaged as to be entirely worthless. About 300 yards from this point the storm demolished another iron windmill, and picked up a heavy handcart, carrying it 600 feet, dropping and breaking it to pieces. By this time the wind was blowing from the west. Half a mile farther on another barn was demolished by being carried a short distance and dropped. From this point the storm traveled easterly, and at a distance of less than a mile unroofed a large warehouse on the bank of the Sacramento River. It then crossed the river in a southeasterly direction, doing some damage. During the storm, which lasted but a few minutes, the wind blew from all points of the compass, commencing from the southeast and returning to the same.

## SAND STORMS.

Sand storms and dust storms occur quite frequently in many portions of the State. Particularly on the southeastern slope of the Sierra and in some of the valleys of southern California do these storms occur. The presence of an area of high pressure over Nevada and Utah, causing strong northerly winds, is probably the prime factor in the formation of these dust storms. As might be expected, the air is highly electrified at such times. Like the "northers" of the great valleys these dust-laden winds are very trying upon people and injurious to stock and crops. Many illustrations could be given, but the following will probably suffice:

## SAND STORM IN SAN LUIS OBISPO COUNTY.

The following report of a remarkable sand storm near Creston, San Luis Obispo County, is furnished by John G. W. and Wilhelmina A. Schulte. The severity of this storm was also noted by many other observers in their monthly reports for June:

"On June 30, 1898, there was an unusually heavy sand storm from 10 a. m. to 8 p. m. The early morning had the appearance of light fog, although no moisture was felt, and it was soon realized that a sand storm was approaching. The clouds of fine dust became so dense that large oak trees 50 yards away could be but indistinctly seen. The air was very still and sultry. The little sunlight visible at times through the dust was white in appearance and much resembled moonlight. In a little while all things had a gray or yellowish coating. Animals seemed affected and were quiet. Not a sound was to be heard; not even the chirping of birds. There was an unpleasant odor with the dust, which resembled buhach.

"This was said to be the severest storm known in the middle section of San Luis Obispo County. It appeared at Paso Robles, in the northern part of the county, about 8 a. m., but was not felt at Creston, 16 miles southeast, until 9.30 a. m. In Creston there was a slight northerly breeze. Maximum temperature, 91°; minimum, 46°; temperature at noon, 86°."

## EARTHQUAKES.

It may be open to question whether the subject of earthquakes should properly be included in a memoir upon climatology. The subject belongs rather to geology. In the absence, however, of any systematic record of seismic phenomena in the State of California, a brief record of the quakes has been kept by the Weather Bureau. There is a well-defined belief among the older residents of California that earthquakes are preceded by a spell of sultry weather, and this is even known by the name of "earthquake weather." There is, however, no known relation between earthquakes and the weather. As shown by the following table, some of the most severe earthquakes have occurred when the conditions of weather were in nowise those which are said to be characteristic. The true causes of earthquakes must be sought elsewhere than in meteorological conditions.

*January, 1897.*—At Niles on the 29th, San Leandro 17th and 23d.

*February, 1897.*—At Descanso on the 16th and 25th.

*May, 1897.*—At Crescent City on the 15th, 23d, and 29th, Edmanton 15th.

*June, 1897.*—On the 20th at Campbell, Centerville, Hollister, North Hill Vineyard, Rio Vista, Sacramento, San Francisco, San Jose, San Leandro, Santa Cruz, and Stockton.

*July, 1897.*—At Castle Pinckney on the 18th.

*August, 1897.*—At Ukiah on the 19th.

*September, 1897.*—At Descanso on the 6th and 22d, Hollister 2d.

*October, 1897.*—At Campbell on the 2d and 17th, Descanso 27th, Niles 2d, San Francisco and San Jose 17th.

*November, 1897.*—At Descanso on the 12th and 22d, Escondido and Fall Brook 22d.

*December, 1897.*—At Niles on the 26th.

*1898.*—The only severe shock experienced was on the 30th of March, when considerable damage resulted at San Francisco, Vallejo, and other points in the central and northern portions; and at Centerville, Alameda County, it was reported the most severe since October 21, 1868.

*January, 1898.*—At Peachland, Sonoma County, at 5.15 a. m. on the 1st.

*February, 1898.*—At Bishop, Inyo County, a light shock on the 6th, and five distinct shocks between 3.30 and 5.30 a. m. on the 15th.

*March, 1898.*—At Descanso on the 3d, Upper Lake 17th; and the following stations reported unusually severe shocks on the 30th, at about 11.42 p. m.: Agnews, Berkeley, Campbell, Fort Ross, Georgetown, Hollister, Iowa Hill, Lytton Springs, Napa, Niles, North San Juan, Oakland, Oleta, Peachland, Rio Vista, Sacramento, San Francisco, San Leandro, Santa Cruz, Stockton, Upper Lake, Vacaville, Vallejo, and West Point.

*April, 1898.*—At Claremont on the 30th, Descanso 21st; Fort Bragg, Mills College, Oakland, Peachland 14th, Pomona 30th, Upper Lake 14th and 15th.

*May, 1898.*—At Cedarville on the 17th and 19th, Hollister 28th. There were frequent shocks during the month at Fort Bragg.

*June, 1898.*—At Descanso on the 23d and 24th, Ukiah 8th, 9th, and 11th, Upper Lake 9th.

*August, 1898*—At Oakland on the 7th, San Leandro 28th and 31st

*October, 1898*.—At Bishop on the 13th, Descanso 30th, San Bernardino 23d, Ukiah 15th.

*November, 1898*.—At Centerville on the 14th, Summerdale 5th.

*December, 1898*—At Centerville and San Leandro on the 7th

*January, 1899*—Light shocks occurred at Napa and Sonoma on the 13th, and at San Bernardino on the 24th.

*March, 1899*.—Light shock at Ukiah on the 7th.

*April, 1899*.—Light shocks at Oakland on the 5th and 30th, Cuyamaca 14th, Hydesville 16th and 18th. On the 30th quite heavy shocks were reported at Alvarado, Campbell, Capitola, Coyote, Gilroy, Glenwood, Hollister, Los Gatos, Niles (Centerville), Pacific Grove, San Francisco, San Leandro, Santa Cruz, Soledad, Stanford University, and Stockton

*May, 1899*.—There was a light shock at Bishop on the 13th

*June, 1899*.—On the 1st, at 11 20 p. m., severe shocks occurred at San Francisco, Niles, Oakland, Stanford University, Capitola, Mills College, Napa, and Livermore. Lighter shocks were also reported, as follows: On the 1st at Campbell, Moreno Dam, Peachland, 3d, Oakland; 5th, Bradley; 11th, Keeler, Porterville, and Milo; 13th, San Francisco, San Jose, and Berkeley; 25th San Miguel.

*July, 1899*.—At 12.10 p. m. on the 6th light shocks occurred at Berkeley, Boulder Creek, Campbell, Capitola, Coyote, Elmwood, Gilroy, Glenwood, Gonzales, Hollister, Lathrop, Le Grand, Los Gatos, Merced, Milbrae, Modesto, Mount Eden, Napa, Niles, Oakland, Pacific Grove, Salinas, San Francisco, San Jose, Santa Cruz, and Stockton. Several severe shocks occurred in the southern portion of the State on the 21st and 22d, followed by lighter ones on the 23d, 28th, and 29th; reports were received from Anaheim, Arcadia, Colton, Duarte, El Cajon, Elsinore, Escondido, Fall Brook, Florence, Los Angeles, North Ontario, Pasadena, Pomona, Redlands, Riverside, San Bernardino, San Diego, San Dimas, San Pedro, Santa Ana, Spadra, and Ventura

*August, 1899*.—The following stations reported light shocks on the 4th and 5th: Ben Lomond, Boulder Creek, Campbell, Capitola, Glenwood, Lathrop, Los Gatos, Napa, Niles, Oakland, San Francisco, San Jose, Santa Cruz, and Tequisquita. There was also a slight shock at San Diego on the 21st

*September, 1899*.—There was a severe shock at San Miguel on the 16th; two light shocks at Needles on the 20th.

*October, 1899*.—Light shocks occurred at Cuyamaca, Peachland, and Santa Rosa on the 12th; Moreno Dam, 11th and 28th.

*November, 1899*.—There was a light shock at Napa on the 16th.

*December, 1899*—On the 25th sharp shocks were experienced throughout southern California; many observers reported the shocks the most severe ever known. Lighter shocks were also experienced frequently from the 25th to the 31st. Reports were received from the following stations: Arcadia, Banning, Claremont, Crafton, Cuyamaca, Duarte, El Cajon, Elsinore, Escondido, Fall Brook, Follows Camp, Girard, Hemet, Indio, La Mesa, Long Beach, Los Angeles, Monte, Moreno Dam, Needles, North Ontario, Norwalk, Ontario, Palm Springs, Pomona, Ravenna, Riverside, San Bernardino, San Diego, San Dimas, San Jacinto, Sierra Madre, Tehachapi, Tustin, and Whittier. Lighter shocks were reported at Chico on the 12th, 13th, 19th, 20th, and at Napa on the 25th.

*January, 1900*.—At Campbell, Niles, and San Leandro on the 14th, Los Gatos 6th, Moreno Dam 28th, Napa 5th, Palm Springs, "frequently during the first part of the month," Peachland 31st, San Jacinto 1st, 2d, 4th, 9th, 13th, 15th, and 27th.

*February, 1900*.—At Claremont on the 2d, Cuyamaca 13th, Petaluma 9th, San Jacinto 7th and 9th.

*March, 1900*—At Claremont on the 21st, Napa, Vacaville, and Vallejo 26th, Peachland 20th, San Jacinto 18th.

*April, 1900.*—At Cuyamaca on the 23d, Fall Brook 9th, Napa 16th, San Jacinto 15th and 16th.

*May, 1900.*—At Mount Eden on the 20th and San Jacinto on the 10th.

*June, 1900.*—At Cuyamaca on the 19th and 20th, Keeler 26th, San Ardo 9th.

*July, 1900.*—At Branscomb on the 12th and 13th, San Diego 23d, San Jose 28th.

*August, 1900.*—At Elsinore on the 18th, Ferndale 16th; Mills College, Niles, and Oakland 31st, San Jacinto 19th, San Jose, Stanford University and Tequisquita Rancho 31st.

*September, 1900.*—At Oakland on the 19th and Tequisquita Rancho on the 28th.

*October, 1900.*—There was a light shock at Tequisquita Rancho on the 24th.

*November, 1900.*—Light shocks occurred at Branscomb on the 8th, Cuyamaca 5th and 19th, Fallbrook 14th, Moreno Dam 19th, Napa 25th, Oakland 24th, Penn Grove 13th.

*December, 1900.*—There was a light shock at San Jose on the 30th.
